# Quasi-periodic oscillations, mass and jets of black holes: XTE J1550-564 and Sgr A* 

Jacob Biemond*<br>Vrije Universiteit, Amsterdam, Section: Nuclear magnetic resonance, 1971-1975<br>*Postal address: Sansovinostraat 28, 5624 JX Eindhoven, The Netherlands<br>Website: http://www.gewis.nl/~pieterb/gravi/ Email: gravi@gewis.nl

#### Abstract

In this paper the recently proposed three tori model for the explanation of three high frequency quasi-periodic oscillations (QPOs) has been applied to black holes. The circular tori are: an outer torus with charge $Q_{0}$, a torus with mass $m_{\mathrm{m}}$ in the middle and an inner torus with charge $Q_{\mathrm{i}}$, whereas the star bears a charge $Q_{s}$. Especially, the gravitational interaction between the torus with mass $m_{\mathrm{m}}$ and the masses of the other two tori has been taken into account in this work.

For the explanation of four low frequency QPOs a special interpretation of the gravitomagnetic theory has again been applied.

Predictions of the new model are compatible with deduced high and low frequency QPOs of the stellar black hole XTE J1550-564 and the supermassive black hole Sgr A*. Moreover, the Lense-Thirring precession frequency for black holes is discussed. Furthermore, it is shown, that a massive torus around Sgr A* may lead to a higher and anisotropic observed mass for the black hole. Finally, the origin of jets is investigated by studying the radial motion of charge in the KerrNewman space-time. It is shown that charge may be bound on a shell slightly outside the ergosphere.

## 1. INTRODUCTION

Quasi-periodic oscillations (QPOs) have been observed for many accreting pulsars, black holes and white dwarfs. Data from pulsars and black holes have been reviewed by, e.g., van der Klis [1]. In this work QPO frequencies of the stellar black hole XTE J1550564 and the Galactic Center black hole $\mathrm{Sgr} \mathrm{A}^{*}$ will be considered more in detail. Recently, Miyoshi et al. [2] distinguished a series of seven QPOs for $\operatorname{Sgr} \mathrm{A}^{*}$, obtained from radio emissions observed by the Very Long Baseline Array (VLBA). Previously, Aschenbach et al. [3, 4] distinguished more than seven QPOs from X-ray flares of $\operatorname{Sgr} \mathrm{A}^{*}$, detected by Chandra in 2000 and by XMM-Newton in 2002.

QPOs are important from the theoretical point of view, for they may originate near the surface of the star, where effects predicted by general relativity may become manifest. Numerous models have been proposed to explain the origin of QPOs, but none is generally accepted. Orbital motions, including general relativistic epicyclic motions, and disk oscillations are the mechanisms most often considered for pulsars and black holes (see for a review, e.g., [1, § $2.8-\S 2.12]$ ). Models involving orbital motions are usually given in terms of four basic formulas following from general relativity (see, e.g., [1]): a Kepler-like orbital frequency of neutral particles, $v_{\mathrm{m}}$, the so-called radial and vertical epicyclic frequencies, $v_{\mathrm{r}}$ and $v_{\mathrm{v}}$, and the standard expression for the Lense-Thirring precession frequency, $v_{\mathrm{LT}}$.

As an example, for pulsars and black holes the so-called relativistic precession model was first proposed by Stella and Vietri (see, e.g., Stella, Vietri and Morsink [5]). In this model three formulas for the QPO frequencies were given. The QPO with the highest
frequency, the so-called upper $\mathrm{kHz} \mathrm{QPO}, v_{\mathrm{u}}$, was identified with a Kepler-like orbital frequency of neutral particles, $v_{\mathrm{m}}$, whereas the lower kHz QPO, $v_{\mathrm{l}}$, was attributed to the so-called periastron precession frequency, defined by $v_{1} \equiv v_{\mathrm{m}}-v_{\mathrm{v}}$. A third lower frequency QPO was identified with the Lense-Thirring precession frequency $v_{\mathrm{LT}}$ of the Kepler-like orbital with frequency $v_{\mathrm{m}}$.

Motivated by the observation of the double peak kHz QPOs, the upper kHz QPO, $v_{\mathrm{u}}$, and the lower kHz QPO for many pulsars, $v_{\mathrm{l}}$, Kluźniak and Abramowicz [6, 7] tried to explain the two highest QPO frequencies of black holes in terms of the Kepler-like orbital frequency, $v_{\mathrm{m}}$, and the radial epicyclic frequency, $v_{\mathrm{r}}$. In addition, they proposed resonances between the frequencies $v_{\mathrm{r}}$ and $v_{\mathrm{m}}$, e.g., $v_{\mathrm{r}}: v_{\mathrm{m}}=3: 1$. Moreover, they identified $v_{\mathrm{u}}$ with $v_{\mathrm{m}}$ and $v_{\mathrm{l}}$ with the beat frequency $v_{\mathrm{m}}-v_{\mathrm{r}}$, resulting in the ratio $v_{\mathrm{u}} / v_{1}=3 / 2$. A related resonance model for XTE J1550-564 was given by Schnittman and Bertschinger [8]. Apart from resonances between the frequencies $v_{\mathrm{r}}$ and $v_{\mathrm{m}}$, additional resonances may occur between $v_{\mathrm{r}}$ and the vertical epicyclic frequency, $v_{\mathrm{v}}$. Several resonances between $v_{\mathrm{r}}$ and $v_{\mathrm{m}}$ or $v_{\mathrm{v}}$ were discussed by Török [9], all resulting into a theoretical integer ratio $v_{\mathrm{u}} / v_{1}$ $=3 / 2$. In addition, he gave a selection of observed values for $v_{\mathrm{u}}$ and $v_{1}$ from four X-ray binary systems containing a black hole (including XTE J1550-564) and for the supermassive black hole $\operatorname{Sgr} A^{*}$, all yielding an approximate ratio $v_{\mathrm{u}} / v_{\mathrm{i}}=3 / 2$.

Compared with other models, we have recently introduced charge as a possible new key ingredient [10]. The high frequency QPOs of white dwarfs, pulsars and black holes are attributed to three orbital frequencies of circular tori around the central star. The first frequency $v_{\mathrm{i}}$ is attributed to an inner torus containing a total electric charge $Q_{\mathrm{i}}$. The sign of the charge of $Q_{\mathrm{i}}$ is assumed to be opposite to the sign of the total charge $Q_{\mathrm{s}}$ of the star or black hole. The second frequency $v_{\mathrm{o}}$ is attributed to an outer torus with total charge $Q_{\mathrm{o}}\left(Q_{\mathrm{o}}\right.$ and $Q_{\mathrm{s}}$ have the same sign). Further, a third torus, containing a total electrically neutral mass $m_{\mathrm{m}}$ (the subscript m stems from middle) is assumed to be present between the two other tori. The latter torus generates a third frequency, the Kepler-like frequency, $v_{\mathrm{m}}$. Furthermore, it is assumed that the high frequencies follow the sequence $v_{\mathrm{i}}$ $>v_{\mathrm{m}}>v_{\mathrm{o}}$. Thus, the frequency $v_{\mathrm{m}}$ in our model is attributed to the second highest QPO frequency, whereas Stella, Vietri and Morsink [5] and Kluźniak and Abramowicz [6, 7] identify $v_{\mathrm{m}}$ with the highest QPO frequency. It is noticed that usually elliptical orbits are considered in the relativistic precession model, whereas in our model only circular orbits are assumed.

By using Coulomb's law and classical mechanics, it has been shown, that an equilibrium between the charge $Q_{\mathrm{s}}$ of the star and the charges $Q_{\mathrm{o}}$ and $Q_{\mathrm{i}}$ in the tori may be possible. Equilibrium is only possible, if the angle between the planes of the tori is not too large. The motion of the tori becomes unstable, when the latter condition is not fulfilled. This instability may (partially) explain the observed instability of the quasiperiodic oscillations and the appearance of the high frequency QPOs $v_{\mathrm{i}}$ and $v_{\mathrm{o}}$. The deduction of the latter frequencies is reviewed in section 2. In addition, expressions for the high frequency QPO, $v_{\mathrm{m}}$, from the third torus containing mass $m_{\mathrm{m}}$, are also discussed in this section. Especially, the gravitational interaction between the torus with mass $m_{\mathrm{m}}$ and the masses of the other two tori has been taken into account in this work.

For the interpretation of the low frequency QPOs of pulsars and black holes another key ingredient may be essential, i.e., a special interpretation of the gravitomagnetic theory, which may be deduced from general relativity [10-14]. In this version the socalled "magnetic-type" gravitational field is identified as a common magnetic field. The resulting Lense-Thirring precession frequencies are deduced in ref. [10] and summarized in section 3. In addition, four new gravitomagnetic precession frequencies follow from this special interpretation (see ref. [10] and review in section 4 of this work). Furthermore, expressions for the parameter $\beta^{*}$, describing the strength of the magnetic field of stars, has been deduced in $[10,13]$ and reviewed in section 5. Data of XTE J1550-564 and Sgr A* are compared with the theoretical predictions in section 6.

It appears that the mass of the black hole Sgr A* is a crucial parameter in the interpretation of the observed QPOs. Ghez, Salim et al. [15, 16] reported masses of (3.7 $\pm$ $0.2) \times 10^{6} m_{\odot}$ and $(4.1 \pm 0.6) \times 10^{6} m_{\odot}$ for the central mass of the Galaxy, respectively. In addition, Schödel, Merrit and Eckart [17] deduced a best-fit black hole mass of (3.6 $+0.2 /-0.4) \times 10^{6} m_{\odot}$. In our calculations a value of $m_{\mathrm{s}}=3.7 \times 10^{6} m_{\odot}$ will be used. From the latter mass the following gravitational radius $r_{\mathrm{g}}$ can be calculated for $\mathrm{Sgr} \mathrm{A}^{*}$

$$
\begin{equation*}
r_{\mathrm{g}} \equiv \frac{G m_{\mathrm{s}}}{c^{2}}=5.465 \times 10^{11} \mathrm{~cm} \tag{1.1}
\end{equation*}
$$

where $G$ is the gravitational constant and $c$ is the velocity of light in vacuum.
The space-time associated with a charged, rotating black hole is described by the KerrNewman metric (see, e.g., Misner, Thorne and Wheeler [18]). In the $t, r, \vartheta$ and $\varphi$ coordinates of Boyer and Lindquist the latter metric is given by

$$
\begin{gather*}
d s^{2}=g_{i j} d x^{i} d x^{j}=\left(1-\frac{2 r_{\mathrm{g}} r-Q_{\mathrm{s}}^{\prime 2} r_{\mathrm{g}}^{2}}{\rho^{2}}\right) c^{2} d t^{2}-\frac{\rho^{2}}{\Delta} d r^{2}-\rho^{2} d \vartheta^{2}  \tag{1.2}\\
-\left(r^{2}+a^{2}+\frac{2 r_{\mathrm{g}} r-Q_{\mathrm{s}}^{\prime 2} r_{\mathrm{g}}^{2}}{\rho^{2}} a^{2} \sin ^{2} \vartheta\right) \sin ^{2} \vartheta d \varphi^{2}+2\left(\frac{2 r_{\mathrm{g}} r-Q_{\mathrm{s}}^{\prime 2} r_{\mathrm{g}}^{2}}{\rho^{2}} a \sin ^{2} \vartheta\right) c d t d \varphi,
\end{gather*}
$$

where $r_{\mathrm{g}}$ is defined in (1.1). The specific angular momentum of the black hole $a$ is defined by $a \equiv S /\left(m_{s} c\right)$ and the dimensionless parameter $Q_{\mathrm{s}}{ }^{\prime}$ by $Q_{\mathrm{s}}{ }^{\prime} \equiv\left(G^{1 / 2} m_{\mathrm{s}}\right)^{-1} Q_{\mathrm{s}}$, whereas $\vartheta$ is the angle between the directions of the angular momentum $\mathbf{S}$ and the position vector $\mathbf{r}$ pointing from the centre of the black hole to a field point $F$. In addition, the quantities $\rho$ and $\Delta$ are defined by

$$
\begin{equation*}
\rho^{2} \equiv r^{2}+a^{2} \cos ^{2} \vartheta \quad \text { and } \quad \Delta \equiv r^{2}-2 r_{\mathrm{g}} r+a^{2}+Q_{\mathrm{s}}^{\prime 2} r_{\mathrm{g}}^{2} . \tag{1.3}
\end{equation*}
$$

When $\Delta=0$ in (1.2), a singularity occurs. The radius of the inner and outer event horizon, $r_{-}$and $r_{+}$, respectively, are then given by

$$
\begin{equation*}
r_{-}=r_{\mathrm{g}}-\left(r_{\mathrm{g}}^{2}-a^{2}-Q_{\mathrm{s}}^{\prime 2} r_{\mathrm{g}}^{2}\right)^{1 / 2}, \quad r_{+}=r_{\mathrm{g}}+\left(r_{\mathrm{g}}^{2}-a^{2}-Q_{\mathrm{s}}^{\prime 2} r_{\mathrm{g}}^{2}\right)^{1 / 2} . \tag{1.4}
\end{equation*}
$$

Another singularity occurs when the metric component $g_{t t}=0$, resulting into

$$
\begin{equation*}
r_{\text {in }}=r_{\mathrm{g}}-\left(r_{\mathrm{g}}^{2}-a^{2} \cos ^{2} \vartheta-Q_{\mathrm{s}}^{\prime 2} r_{\mathrm{g}}^{2}\right)^{1 / 2}, \quad r_{\text {out }}=r_{\mathrm{g}}+\left(r_{\mathrm{g}}^{2}-a^{2} \cos ^{2} \vartheta-Q_{\mathrm{s}}^{\prime 2} r_{\mathrm{g}}^{2}\right)^{1 / 2}, \tag{1.5}
\end{equation*}
$$

where $r_{\text {in }}$ and $r_{\text {out }}$ are the radii of the inner and outer horizon of the so-called ergosphere, respectively.

Furthermore, the stability condition for bound circular orbits derived by Dadhich and Kale [19] will be considered. For a prograde circular equatorial orbit in KerrNewman space-time it can be written as

$$
\begin{gather*}
F \equiv r_{\mathrm{g}} r\left(-6 r_{\mathrm{g}} r+r^{2}+9 Q_{\mathrm{s}}^{\prime 2} r_{\mathrm{g}}^{2}-3 a^{2}\right)  \tag{1.6}\\
-4 Q_{\mathrm{s}}^{\prime 2} r_{\mathrm{g}}^{2}\left(Q_{\mathrm{s}}^{\prime 2} r_{\mathrm{g}}^{2}-a^{2}\right)+8 a\left(r_{\mathrm{g}} r-Q_{\mathrm{s}}^{\prime 2} r_{\mathrm{g}}^{2}\right)^{3 / 2} \geq 0 .
\end{gather*}
$$

In Schwarschild space-time where both $a=0$ and $Q_{s}{ }^{\prime}=0$, stable orbits are obtained for $r$ $=0$ and the innermost circular orbit $r_{\text {ISCO }}=6 r_{\mathrm{g}}$. In the so-called extreme limit of the Reissner-Nordstrøm space-time ( $a=0$ and $Q_{\mathrm{s}}{ }^{\prime}=1$ ) stable orbits are obtained for $r=r_{\mathrm{g}}$ and $r_{\text {ISCO }}=4 r_{\mathrm{g}}$. In the extreme limit of Kerr space-time $\left(a=r_{\mathrm{g}}\right.$ and $\left.Q_{\mathrm{s}}{ }^{\prime}=0\right)$ only one stable orbit is obtained for $r_{\text {ISCO }}=r_{\mathrm{g}}$. When a value of $r_{\text {ISCO }}$ is known in Kerr space-time the value of $a$ follows from (1.6) for $F=0$.

The adopted value of mass $m_{\mathrm{s}}$ of $\mathrm{Sgr} \mathrm{A}^{*}$ is discussed in section 7. Expressions for an effective mass $m$ (eff), related to $m_{s}$, are deduced for two orientations of a massive torus with respect to the orbital plane of a star orbiting around $\mathrm{Sgr} \mathrm{A}^{*}$. It is appears that the value of $m$ (eff) may become higher than $m_{\mathrm{s}}$ and anisotropic, depending on the orientations of the tori. Finally, in order to investigate the origin of jets, the radial motion of a small charge, say a proton, is investigated in section 8. It is shown, that the proton may be at rest at a distance slightly larger than the radius $r_{\text {out }}$ of (1.5). A discussion of the QPO results is given in section 9. Conclusions are drawn in section 10.

## 2. HIGH FREQUENCY QUASI-PERIODIC OSCILLATIONS

In this section a review is given of the high frequency QPOs, recently presented by Biemond [10]. The high frequency QPOs are attributed to orbital frequencies of circular tori around a central black hole. Three different high frequency QPOs will be distinguished: the first frequency $v_{\mathrm{i}}$ is attributed to an inner torus with radius $r_{i}$, containing a total charge $Q_{\mathrm{i}}$. The sign of the charge of $Q_{\mathrm{i}}$ is assumed to be opposite to the sign of the total charge $Q_{\mathrm{s}}$ of the star or black hole. The second frequency $v_{\mathrm{o}}$ is attributed to an outer torus with radius $r_{\mathrm{o}}$, containing a total charge $Q_{\mathrm{o}}$ ( $Q_{\mathrm{o}}$ and $Q_{\mathrm{s}}$ have the same sign). Further, a third torus with radius $r_{\mathrm{m}}$, containing a total electrically neutral mass $m_{\mathrm{m}}$ (the subscript m stems from middle), is assumed to be present between the two other tori. Thus, it is assumed that $r_{\mathrm{i}}<r_{\mathrm{m}}<r_{\mathrm{o}}$.

### 2.1 High frequency QPO $v_{i}$, due to the inner torus with charge $Q_{i}$

First, the calculation of the high frequency QPO $v_{\mathrm{i}}$ will be reviewed. We consider a circular torus containing a total charge $Q_{0}$, lying in an $x-y$ plane at distance $r_{0}$ from the origin $O$, as shown in figure 1. A radius vector $\mathbf{r}_{i}$ from $O$ to a point charge $d Q_{i}$ at field point $F$ is fixed by the spherical coordinates $r_{\mathrm{i}}, \theta$ and $\varphi=0$. The absolute value of the position vector $\mathbf{r}$ from $F$ to a point charge $d Q_{\mathrm{o}}$ in the torus with charge $Q_{\mathrm{o}}$ is then given by

$$
\begin{equation*}
r=r_{\mathrm{o}}\left(1+x^{2}-2 x \sin \theta \cos \varphi\right)^{1 / 2}, \tag{2.1}
\end{equation*}
$$

where $x$ is defined by $x \equiv r_{\mathrm{i}} / r_{\mathrm{o}}$.
Using Coulomb's law, the component of the Coulomb force $d \mathbf{F}_{\text {io }}$ in the direction of $\mathbf{r}_{\mathrm{i}}$ between the point charge $d Q_{\mathrm{o}}$ and point charge $d Q_{\mathrm{i}}$ at field point $F$ can then be calculated to be

$$
\begin{equation*}
d \mathbf{F}_{\mathrm{io}}=\frac{d Q_{\mathrm{o}} d Q_{\mathrm{i}}}{r_{\mathrm{o}}^{2}} \frac{x-\sin \theta \cos \varphi}{\left(1+x^{2}-2 x \sin \theta \cos \varphi\right)^{3 / 2}} \mathbf{i}_{\mathrm{i}}, \tag{2.2}
\end{equation*}
$$

where the unit vector $\mathbf{i}_{\mathrm{i}}$ is given by $\mathbf{i}_{\mathrm{i}}=\mathbf{r}_{\mathrm{i}} /\left|\mathbf{r}_{\mathrm{i}}\right|$. It is noted that an additional contribution to the Coulomb force, $d \mathbf{F}_{\mathrm{io}}{ }^{\prime}$, perpendicular to $d \mathbf{F}_{\mathrm{io}}$ and lying in the $x-z$ plane, has been neglected (It can be shown, that $d \mathbf{F}_{\mathrm{io}}{ }^{\prime}=0$ for field points $F$ lying on the $z$ or $x$ axis). The following relation applies, when the charge distribution in the torus with total charge $Q_{o}$ is homogeneous

Figure 1. Spherical coordinates $r_{\mathrm{i}}, \theta$ and $\varphi=0$ of the field point $F$ relative to the origin $O$ and the spherical coordinates $r_{\mathrm{o}}, \theta=90^{\circ}$ and $\varphi=\varphi$ of point charge $d Q_{\mathrm{o}}$ (with point mass $d m_{\mathrm{o}}$ ), lying in the $x-y$ plane. The angle between the unit vector $\mathbf{s}$, defined as $\mathbf{s} \equiv \boldsymbol{\Omega}_{\mathrm{s}} / \Omega_{\mathrm{s}}$, and the unit vector $\mathbf{n}_{\mathrm{o}}$ in the direction of the rotation axis of the torus with total charge $Q_{0}$ is denoted by $\delta_{0}$.

$$
\begin{equation*}
d Q_{\mathrm{o}}=\frac{Q_{\mathrm{o}}}{2 \pi} d \varphi . \tag{2.3}
\end{equation*}
$$

Substitution of the expression for $d Q_{\mathrm{o}}$ from (2.3) into (2.2), followed by integration of $\varphi$ from 0 to $\pi$ yields the following expression for the total Coulomb force $\mathbf{F}_{\text {io }}$ at field point $F$ from the torus with total charge $Q_{0}$

$$
\begin{equation*}
\mathbf{F}_{\mathrm{io}}=\frac{Q_{0} d Q_{\mathrm{i}}}{\pi r_{\mathrm{o}}^{2}} \int_{0}^{\pi} \frac{x-\sin \theta \cos \varphi}{\left(1+x^{2}-2 x \sin \theta \cos \varphi\right)^{3 / 2}} d \varphi \mathbf{i}_{\mathrm{i}}=-f \frac{Q_{\mathrm{o}} d Q_{\mathrm{i}}}{r_{\mathrm{o}}^{2}} \mathbf{i}_{\mathrm{i}} . \tag{2.4}
\end{equation*}
$$

Since the charge distribution in the circular torus is symmetric about $\varphi=0$, the result of the integration for $\mathbf{F}_{\text {io }}$ yields no $y$ component for $\varphi=0$. The function $f$ in (2.4) is defined by

$$
\begin{equation*}
f \equiv \frac{-1}{\pi x\left(1+x^{2}+2 x \sin \theta\right)^{1 / 2}}\left\{K(k)-\frac{\left(1-x^{2}\right) E(k)}{1+x^{2}-2 x \sin \theta}\right\} . \tag{2.5}
\end{equation*}
$$

The integral of (2.4) can be calculated by using complete elliptic integrals of the first kind and second kind, $K(k)$ and $E(k)$, respectively. See for the properties of these integrals, e.g., [20, § 2.57, § 8.11-§8.12]. The modulus $k$ of the elliptic integrals is given by

$$
\begin{equation*}
k^{2}=\frac{4 x \sin \theta}{1+x^{2}+2 x \sin \theta} . \tag{2.6}
\end{equation*}
$$

We will treat some properties of this remarkable function $f$ below.
If the star bears a point charge $Q_{\mathrm{s}}$, a point charge $d Q_{\mathrm{i}}$ in the torus with total charge $Q_{i}$ is subjected to the following Coulomb force $\mathbf{F}_{\text {is }}$

$$
\begin{equation*}
\mathbf{F}_{\mathrm{is}}=\frac{Q_{\mathrm{s}} d Q_{\mathrm{i}}}{r_{\mathrm{i}}^{2}} \mathbf{i}_{\mathrm{i}}, \tag{2.7}
\end{equation*}
$$

where $\mathbf{i}_{\mathrm{i}}$ is again given by $\mathbf{i}_{\mathrm{i}}=\mathbf{r}_{\mathrm{i}} /\left|\mathbf{r}_{\mathrm{i}}\right|$. It can be shown, however, that relation (2.7) remains
valid for the interaction between point charge $d Q_{\mathrm{i}}$ and a sphere with homogeneous charge density and total charge $Q_{\mathrm{s}}$ for any value of $r_{\mathrm{i}} \geq r_{\mathrm{s}}$. If equilibrium between the Coulomb forces $\mathbf{F}_{\text {io }}$ and $\mathbf{F}_{\text {is }}$ exists, combination of (2.4) and (2.7) yields the following relation

$$
\begin{equation*}
Q_{\mathrm{s}}=x^{2} f Q_{\mathrm{o}} \tag{2.8}
\end{equation*}
$$

One can also say that the electric fields $\mathbf{F}_{\text {io }} / d Q_{\mathrm{i}}$ due to $Q_{\mathrm{o}}$ (see (2.4)) and $\mathbf{F}_{\text {is }} / d Q_{\mathrm{i}}$ due to $Q_{s}$ (see (2.7)) compensate each other. Then, the resulting electric field at field point $F$ is zero. Furthermore, it is noticed that equilibrium is only possible for a positive value of the function $f$. As an illustration, we calculate the value of $f$ in some cases.

It appears that the value $\theta=90^{\circ}$ is of particular interest. In that case, the modulus $k$ from (2.6) reduces to $k^{2}=4 x /(1+x)^{2}$ and the following simplified expression for $f$ can be obtained from (2.5)

$$
\begin{equation*}
f=\frac{-1}{\pi x}\left\{\frac{K(k)}{1+x}-\frac{E(k)}{1-x}\right\}=\frac{-2}{\pi x}\left\{K(x)-\frac{E(x)}{1-x^{2}}\right\} \equiv f(x) \tag{2.9}
\end{equation*}
$$

In deriving the right hand side of (2.9), use has been made of the following properties of the complete elliptic integrals: $K(k)=(1+x) K(x)$ and $E(k)=\{2 E(x) /(1+x)\}-(1-x) K(x)$ (see, e.g., [20, § 8.12]).

A second case follows from (2.5), when $f \equiv f_{0}=0$

$$
\begin{equation*}
K\left(k_{0}\right)=\frac{\left(1-x_{0}^{2}\right) E\left(k_{0}\right)}{1+x_{0}^{2}-2 x_{0} \sin \theta_{0}} \tag{2.10}
\end{equation*}
$$

An additional relation between $k_{0}, x_{0}$ and $\theta_{0}$ is given by (2.6). When a value for $k_{0}$ is chosen $K\left(k_{0}\right)$ and $E\left(k_{0}\right)$ can be found. Combination of (2.6) and (2.10) then yields the values for $x_{0}$ and $\theta_{0}$. Further, it is noticed that $k_{0}$ and $k$ can be written as

$$
\begin{equation*}
k_{0}=\sin \alpha_{0} \text { and } k=\sin \alpha, \tag{2.11}
\end{equation*}
$$

where $\alpha_{0}$ and $\alpha$ are the so-called modular angles.
In table 1 a number of parameters occurring in (2.5), (2.6), (2.9), (2.10) and (2.11) are given (see more results in ref. [10] for additional high values of $\alpha_{0}$ ). In order to calculate the various parameters the following procedure has been followed. First, a value of $\alpha_{0}$ is chosen and $k_{0}$ is calculated from (2.11a). When $k_{0}$ is known, $K\left(k_{0}\right)$ and $E\left(k_{0}\right)$ are calculated from their respective series expansions up to sixth order terms (see, e.g., [20, $\S 8.11]$ ). Then, $x_{0}$ and $\theta_{0}$ can be calculated from (2.6) and (2.10). Subsequently, choosing $\theta=90^{\circ}$ and $x=x_{0}$, the values of $k$ and $\alpha$ can be calculated from (2.6) and (2.11b), respectively. When $k$ is known, the complete elliptic integrals $K(k)$ and $E(k)$ are also calculated from their respective series expansions up to sixth order terms (see, e.g., [20, § 8.11]). For values of $\alpha_{0}$ between, say $\alpha_{0}=30^{\circ}$ and $\alpha_{0}=55^{\circ}$, terms higher than sixth order become important. Therefore, less significant digits have been given for the calculated parameters in this range. It can be shown that the value of $\sin \theta_{0}$ approaches to $(2 / 3)^{1 / 2}$ (or $\theta_{0} \rightarrow 54.74^{\circ}$ ) for small values of $\alpha_{0}$. Finally, the value for $f$ can be calculated from (2.9). It is noticed that for $x=x_{0}$ the charge system is only stable, if $\theta$ is lying in the interval $\theta_{0}<\theta \leq 90^{\circ}$, corresponding to the interval $f_{0}<f \leq f(x)$ for $f$.

A third case follows from (2.6), when $\theta=0^{\circ}$. A value $k=0$ is then obtained. Introduction of the quantities $\theta=0^{\circ}$ and $k=0$ into (2.5) yields for $f$

$$
\begin{equation*}
f=-\frac{x}{\left(1+x^{2}\right)^{3 / 2}} . \tag{2.12}
\end{equation*}
$$

Note that $f$ is negative for a positive value of $x$, so that no equilibrium can exist for this charge configuration. Summing up, the factor $f$ is an important parameter with respect to the stability of the system.

In order to illustrate the property of sign change of function $f$, the following example will be considered. The plane of the torus with total charge $Q_{\mathrm{i}}$ and the plane of the torus with total charge $Q_{o}$ are supposed to have the $y$ axis in common. The charge elements $d Q_{\mathrm{i}}$ at the field point $F$ in the $x-z$ plane with the spherical coordinates $r_{\mathrm{i}}, \theta=\theta$ and $\varphi=0$ (see figure 2) and at the point with coordinates $r_{\mathrm{i}}, \theta=180^{\circ}-\theta$ and $\varphi=180^{\circ}$ are less firmly bound (or in a non-bound state when $\theta<\theta_{0}$ ). However, the charges $d Q_{\mathrm{i}}$ at the coordinates $r_{\mathrm{i}}, \theta=90^{\circ}$ and $\varphi=90^{\circ}$ and $r_{\mathrm{i}}, \theta=90^{\circ}$ and $\varphi=270^{\circ}$ are in a bound state. As a result, the current flows in the tori may be interrupted twice per revolution around the star, so that their frequencies may become manifest. From the results in table 1 follows that values for $\theta_{0}$ are only a little bit smaller than $90^{\circ}$ when $x$ approaches to unity. The stability range for $\theta$ is thus rather limited for large values of $x$. In order to obtain a stable situation between the tori with charges $Q_{\mathrm{i}}$ and $Q_{\mathrm{o}}$, respectively, the angle $\Delta=90^{\circ}-\theta$ between the unit vectors $\mathbf{n}_{\mathrm{i}}$ and $\mathbf{n}_{\mathrm{o}}$ (see figure 2) has to be small. The sign change of the function $f$ might thus explain the manifestation of the high frequency QPOs $v_{\mathrm{i}}$ and $v_{\mathrm{o}}$. The occurrence of the high frequency $\mathrm{QPO} v_{\mathrm{m}}$, however, is not explained by this mechanism. For simplicity reasons, it will be assumed in this work that the observed orbital frequencies $v_{\mathrm{i}}, v_{\mathrm{o}}$ and $v_{\mathrm{m}}$ represent the number of complete revolutions per second around the star with charge $Q_{s}$.

Figure 2. Orbits of the tori with total charge $Q_{\mathrm{o}}$ (red) and $Q_{\mathrm{i}}$ (blue), respectively. The direction of the positive $z$ axis of the coordinate system is chosen along the rotation axis of the torus with charge $Q_{0}$. The unit vector in this direction is denoted by $\mathbf{n}_{0}$. The direction of the rotation axis of the torus with charge $Q_{\mathrm{i}}$ with unit vector $\mathbf{n}_{\mathrm{i}}$ is chosen in the $x-z$ plane. The angle between $\mathbf{n}_{0}$ and $\mathbf{n}_{\mathrm{i}}$ is given by $\Delta$. The field point $F$ with spherical coordinates $r_{\mathrm{i}}, \theta$ and $\varphi=0$ is shown (see also text).

For the case considered in figure 2, the value of $f$ can be calculated at the field point $F$ of any point charge $d Q_{\mathrm{i}}$. For example, for $\theta=\theta_{0}$ at the field points $F\left(r_{\mathrm{i}}, \theta_{0}, \varphi=0\right)$ and $F\left(r_{\mathrm{i}}, \theta_{0}, \varphi=180^{\circ}\right) f=f_{0}=0$ and for both field points $F\left(r_{\mathrm{i}}, \theta=90^{\circ}, \varphi=90^{\circ}\right)$ and $F\left(r_{\mathrm{i}}\right.$, $\left.\theta=90^{\circ}, \varphi=270^{\circ}\right) f=f(x)$ from (2.9). Likewise, other values for $f$ can be calculated from (2.5). Subsequently, the average value of $f$ over the whole orbit with total charge $Q_{i}$ could be calculated. In our calculations, however, we will approximate the average value of $f$ over the whole orbit, $f(\bar{x})$, by $f(\bar{x})=1 / 2\left\{f_{0}+f(x)\right\}=1 / 2\{0+f(x)\}=1 / 2 f(x)$.

Table 1. Calculated values for $k_{0}, x_{0}, \theta_{0}, g_{0}$ and $f_{0}\left(f_{0}=0\right)$, together with the values for $K\left(k_{0}\right)$ and $E\left(k_{0}\right)$ on the upper line. Choosing $\theta=90^{\circ}$ and $x=x_{0}$, one obtains the values for $k, K(k), E(k), f(x)$ and $g(x)$. These values have been given on the lower line.

| $\alpha_{0}$ | $k_{0}$ | $K\left(k_{0}\right)$ | $E\left(k_{0}\right)$ | $x_{0}$ | $\theta_{0}\left({ }^{\circ}\right)$ | $f_{0}$ | $g_{0}$ |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |

In deriving (2.8), only Coulomb forces have been taken into account. When the gravitation law of Newton and the centrifugal force are also included, a more general description is obtained. When all these forces between a point mass $d m_{\mathrm{i}}$ with charge $d Q_{\mathrm{i}}$ in the inner torus, charge $Q_{\mathrm{s}}$ in the star and a charge $Q_{\mathrm{o}}$ in the outer torus are in equilibrium, the following relation applies

$$
\begin{equation*}
\frac{d m_{\mathrm{i}} \mathrm{v}_{\mathrm{i}}^{2}}{r_{\mathrm{i}}}=\frac{d m_{\mathrm{i}} G m_{\mathrm{s}}}{r_{\mathrm{i}}^{2}}-\frac{d Q_{\mathrm{i}} Q_{\mathrm{s}}}{r_{\mathrm{i}}^{2}}+f \frac{d Q_{\mathrm{i}} Q_{\mathrm{o}}}{r_{\mathrm{o}}^{2}}, \tag{2.13}
\end{equation*}
$$

where $\mathrm{v}_{\mathrm{i}}$ is the velocity of $d m_{\mathrm{i}}$ moving in a circular orbit with radius $r_{\mathrm{i}}$ around the star with mass $m_{\mathrm{s}}$. The charge $Q_{0}$ and mass $m_{0}$ both move in a circular orbit with radius $r_{\mathrm{o}}$ around the star $\left(r_{\mathrm{i}}<r_{\mathrm{o}}\right)$. It is noticed that the gravitational attraction between the masses $m_{\mathrm{i}}$ and $m_{\mathrm{o}}$ in the tori and Lorentz forces in the considered system have been neglected. Moreover, no general relativistic effects have been taken into account in the derivation of (2.13). Starting from a Kerr-Newman space-time, Aliev and Galtsov [21] considered the
latter effects for the binary system of a charged star and a charged mass moving in a circular orbit around that star. As a result, equation (2.13) can only be considered as a first order approximation.

For a homogeneous mass and charge distribution in the torus with a total mass $m_{\mathrm{i}}$ and a total charge $Q_{i}$, respectively, the following relation applies

$$
\begin{equation*}
\frac{d Q_{\mathrm{i}}}{d m_{\mathrm{i}}}=\frac{Q_{\mathrm{i}}}{m_{\mathrm{i}}} \tag{2.14}
\end{equation*}
$$

Then, from (2.13) and (2.14) the following expression for the high frequency $v_{i}$ for a point mass $d m_{\mathrm{i}}$ with charge $d Q_{\mathrm{i}}$ in the torus with a total charge $Q_{\mathrm{i}}$ can be calculated

$$
\begin{equation*}
v_{\mathrm{i}}=\frac{1}{2 \pi}\left[\frac{G m_{\mathrm{s}}}{r_{\mathrm{i}}^{3}}\left\{1-\frac{m_{\mathrm{s}}}{m_{\mathrm{i}}} Q_{\mathrm{i}}^{\prime}\left(Q_{\mathrm{s}}^{\prime}-x^{2} f Q_{\mathrm{o}}^{\prime}\right)\right\}\right]^{1 / 2} \tag{2.15}
\end{equation*}
$$

where $Q_{\mathrm{i}}{ }^{\prime}$ is defined by the dimensionless quantity $Q_{\mathrm{i}}{ }^{\prime} \equiv\left(G^{1 / 2} m_{\mathrm{s}}\right)^{-1} Q_{\mathrm{i}}, Q_{\mathrm{s}}{ }^{\prime}$ by $Q_{\mathrm{s}}{ }^{\prime} \equiv\left(G^{1 / 2} m_{\mathrm{s}}\right)^{-1}$ $Q_{\mathrm{s}}$ and so on. It is to be expected that the factor $m_{\mathrm{s}} / m_{\mathrm{i}}$ on the right hand side of (2.15) is large. In this work it will be assumed that the difference $\left(Q_{\mathrm{s}}-x^{2} f Q_{\mathrm{o}}\right)$ is small, so that relation (2.8) remains approximately valid. The charge dependent contribution on the right hand side of (2.15) may then be positive or negative. As a result, the orbital frequency $v_{i}$ may thus be larger or smaller than the corresponding Kepler frequency $(2 \pi)^{-1}\left(G m_{\mathrm{s}} / r_{\mathrm{i}}^{3}\right)^{1 / 2}$.

### 2.2 High frequency QPO $v_{0}$, due to the outer torus with charge $Q_{0}$

The high frequency QPO $v_{i}$ of (2.15) has been calculated for an inner torus with charge $Q_{\mathrm{i}}$ and radius $r_{\mathrm{i}}$. Analogously, a high frequency QPO $v_{\mathrm{o}}$ can be deduced, due to an outer torus with charge $Q_{\mathrm{o}}$ and radius $r_{\mathrm{o}}\left(r_{\mathrm{o}}>r_{\mathrm{i}}\right)$. We now consider a circular torus containing a total charge $Q_{\mathrm{i}}$, lying in another $x-y$ plane at distance $r_{\mathrm{i}}$ from the origin $O$ (compare with figure 1). A radius vector $\mathbf{r}_{0}$ from $O$ to field point $F$ is fixed by the spherical coordinates $r_{0}, \theta$ and $\varphi=0$. The absolute value of the position vector $\mathbf{r}$ from $F$ to a point charge $d Q_{i}$ in the torus with charge $Q_{i}$ is then also given by (2.1).

Using Coulomb's law, Newton's gravitation law and the centrifugal force, the following expression for the frequency $v_{\mathrm{o}}$ for a point mass $d m_{\mathrm{o}}$ with point charge $d Q_{\mathrm{o}}$ in the torus can be calculated (see for a detailed calculation ref. [10])

$$
\begin{equation*}
v_{\mathrm{o}}=\frac{1}{2 \pi}\left[\frac{G m_{\mathrm{s}}}{r_{\mathrm{o}}^{3}}\left\{1-\frac{m_{\mathrm{s}}}{m_{\mathrm{o}}} Q_{\mathrm{o}}^{\prime}\left(Q_{\mathrm{s}}^{\prime}+g Q_{\mathrm{i}}^{\prime}\right)\right\}^{1 / 2}\right. \tag{2.16}
\end{equation*}
$$

where $m_{0}$ and $Q_{0}$ are the total mass and the total charge in the outer torus of radius $r_{0}$, respectively. The dimensionless quantity $Q_{\mathrm{o}}{ }^{\prime}$ is defined by $Q_{\mathrm{o}}{ }^{\prime} \equiv\left(G^{1 / 2} m_{\mathrm{s}}\right)^{-1} Q_{\mathrm{o}}$ and so on. It is to be expected that the factor $m_{\mathrm{s}} / m_{\mathrm{o}}$ on the right hand side of (2.16) is large. In this work it will be assumed that the sum $\left(Q_{\mathrm{s}}+g Q_{\mathrm{i}}\right)$ is small, so that

$$
\begin{equation*}
Q_{\mathrm{s}} \approx-g Q_{\mathrm{i}} \tag{2.17}
\end{equation*}
$$

In principle, the charge dependent contribution on the right hand side of (2.16) may thus be positive or negative. The orbital frequency $v_{0}$ may thus be larger or smaller than the corresponding Kepler frequency $(2 \pi)^{-1}\left(G m_{\mathrm{s}} / r_{\mathrm{o}}^{3}\right)^{1 / 2}$.

The function $g$ in (2.16) is defined by

$$
\begin{equation*}
g \equiv \frac{1}{\pi\left(1+x^{2}+2 x \sin \theta\right)^{1 / 2}}\left\{K(k)+\frac{\left(1-x^{2}\right) E(k)}{1+x^{2}-2 x \sin \theta}\right\} . \tag{2.18}
\end{equation*}
$$

The quantity $g$ of (2.18) can also be calculated by using the complete elliptic integrals of the first kind and second kind, $K(k)$ and $E(k)$, respectively. See for the properties of these integrals, e.g., [20, § 2.57, § 8.11-§8.12]. The modulus $k$ of the elliptic integrals is again given by (2.6).

The general expression $g$ of (2.18) will now be evaluated in two cases. For $\theta=90^{\circ}$, the modulus $k$ of (2.6) again reduces to $k^{2}=4 x /(1+x)^{2}$, whereas $g$ of (2.18) reduces to

$$
\begin{equation*}
g=\frac{1}{\pi}\left\{\frac{K(k)}{1+x}+\frac{E(k)}{1-x}\right\}=\frac{2}{\pi}\left\{\frac{E(x)}{1-x^{2}}\right\} \equiv g(x) . \tag{2.19}
\end{equation*}
$$

In deriving (2.19), use has again been made of the relations: $K(k)=(1+x) K(x)$ and $E(k)=$ $\{2 E(x) /(1+x)\}-(1-x) K(x)$ (see, e.g., [20, § 8.12]). Taking $x=x_{0}, \theta_{0}, k_{0}$ from table $1, g_{0}$ can be calculated from (2.18). Likewise, $g(x)$ can be obtained by inserting $x=x_{0}$ and $k$ from table 1 into (2.19). Results for $g_{0}$ and $g(x)$ have been added to table 1 for a number of cases. It is noticed that values for $g$ are always positive, whereas the value of $f$ from (2.5) may become negative (see, e.g., (2.12)).

Analogously to the method followed for $f(\bar{x})$, from (2.18) an average value for $g$ can be calculated. For the case considered in figure 2, the value of $g$ could be calculated at the field point $F$ of any point charge $d Q_{\mathrm{o}}$. Subsequently, the average value of $g$ over the whole orbit with total charge $Q_{\mathrm{o}}$ could be deduced. Utilizing (2.19), in our calculations we will approximate $\bar{g}(\bar{x})$ by $\bar{g}(\bar{x})=1 / 2\left\{g_{0}+g(x)\right\}$.

Using (2.8) and (2.17), it is possible to calculate the total charge $Q_{\text {tot }}$ of the system. One obtains

$$
\begin{equation*}
Q_{\mathrm{tot}}=Q_{\mathrm{s}}+Q_{\mathrm{i}}+Q_{\mathrm{o}}=\left(1-\frac{1}{g}+\frac{1}{x^{2} f}\right) Q_{\mathrm{s}} \tag{2.20}
\end{equation*}
$$

This relation may be helpful to understand the loading mechanism of a star. Suppose, for example, that the quantity $x$ will increase as a result of compression of the outer torus, due to accretion. Then, it follows from (2.20) and data in table 1 , that the quantity $\{1-1 / g$ $\left.+1 /\left(x^{2} f\right)\right\}$ becomes less positive. Assuming that $Q_{\mathrm{tot}}$ is constant and that the charge $Q_{\mathrm{s}}$ is positive, the amount of positive charge $Q_{\mathrm{s}}$ will increase and positive charge must flow to the star. As an additional consequence, the Lorentz force will generate a toroidal current in the star, when the positive charge enters the star at the equator.

### 2.3 High frequency QPO $v_{m}$, due to the middle torus with mass $m_{m}$

Finally, the orbital frequency $v_{\mathrm{m}}$ for a point mass $d m_{\mathrm{m}}$ in a circular torus containing a homogeneous electrically neutral mass distribution with total mass $m_{\mathrm{m}}$ can be shown to be (compare with, e.g., Aliev and Galtsov [21])

$$
\begin{equation*}
v_{\mathrm{m}}=\frac{1}{2 \pi}\left(\frac{G m_{\mathrm{s}}}{r_{\mathrm{m}}^{3}}\right)^{1 / 2} \frac{1}{1+\frac{S}{c^{2} m_{\mathrm{s}}}\left(\frac{G m_{\mathrm{s}}}{r_{\mathrm{m}}^{3}}\right)^{1 / 2}}=\frac{1}{2 \pi}\left(\frac{G m_{\mathrm{s}}}{r_{\mathrm{m}}^{3}}\right)^{1 / 2} f_{\mathrm{s}}, \tag{2.21}
\end{equation*}
$$

where $r_{\mathrm{m}}$ is the radius of the torus with mass $m_{\mathrm{m}}$. It is noticed that equation (2.21) applies to prograde motion of $d m_{\mathrm{m}}$ in the equatorial plane around the star. This Kepler-like frequency $v_{\mathrm{m}}$ was used by many authors (see, e.g., [4, 5, 8-10]). For white dwarfs and
pulsars the relativistic factor $f_{\mathrm{S}}$ in (2.21) depending on the angular momentum $S$ usually approaches unity, so that the radius $r_{\mathrm{m}}$ can be approximated by the Kepler radius $r_{\mathrm{K}}$

$$
\begin{equation*}
r_{\mathrm{K}}=\left\{\frac{G m_{\mathrm{s}}}{\left(2 \pi \nu_{\mathrm{m}}\right)^{2}}\right\}^{1 / 3} . \tag{2.22}
\end{equation*}
$$

However, the latter approximation is probably not valid for the supermassive black hole Sgr A*.

Furthermore, the contributions from the gravitational interactions between the mass $m_{\mathrm{m}}$ in the torus with radius $r_{\mathrm{m}}$ in the middle and masses $m_{\mathrm{i}}$ and $m_{\mathrm{o}}$ in the tori with radii $r_{\mathrm{i}}$ and $r_{0}$, respectively, can be accounted for. Application of the same method followed in the deduction of (2.15) and (2.16), yields the following expression for the frequency $v_{\mathrm{m}}$

$$
\begin{equation*}
v_{\mathrm{m}}=\frac{1}{2 \pi}\left\{\frac{G m_{\mathrm{s}}}{r_{\mathrm{m}}^{3}}\left(1+g\left(x_{\mathrm{i}}\right) \frac{m_{\mathrm{i}}}{m_{\mathrm{s}}}-x_{\mathrm{o}}^{2} f\left(x_{\mathrm{o}}\right) \frac{m_{\mathrm{o}}}{m_{\mathrm{s}}}\right)\right\}^{1 / 2}, \tag{2.23}
\end{equation*}
$$

where $x_{\mathrm{i}}$ and $x_{\mathrm{o}}$ are defined by $x_{\mathrm{i}} \equiv r_{\mathrm{i}} / r_{\mathrm{m}}$ and $x_{\mathrm{o}} \equiv r_{\mathrm{m}} / r_{\mathrm{o}}$. It is stressed that equation (2.23) applies to the case where all tori with mass $m_{\mathrm{i}}, m_{\mathrm{m}}$ and $m_{\mathrm{o}}$ are lying in the same plane. The quantities $f\left(x_{\mathrm{o}}\right)$ and $g\left(x_{\mathrm{i}}\right)$ in (2.23) can be found from (2.9) and (2.19), respectively

$$
\begin{equation*}
f\left(x_{\mathrm{o}}\right)=\frac{-2}{\pi x_{\mathrm{o}}}\left\{K\left(x_{\mathrm{o}}\right)-\frac{E\left(x_{\mathrm{o}}\right)}{1-x_{\mathrm{o}}^{2}}\right\}, \quad g\left(x_{\mathrm{i}}\right) \equiv \frac{2}{\pi}\left\{\frac{E\left(x_{\mathrm{i}}\right)}{\left(1-x_{\mathrm{i}}^{2}\right)}\right\} . \tag{2.24}
\end{equation*}
$$

It is noticed that the velocities $\mathrm{v}_{\mathrm{i}}$ in (2.13), and the corresponding velocities $\mathrm{v}_{\mathrm{m}}$ of $d m_{\mathrm{m}}$ and $\mathrm{v}_{\mathrm{o}}$ of $d m_{\mathrm{o}}$ moving in a respective circular orbit of radius $r_{\mathrm{m}}$ and $r_{\mathrm{o}}$ around the star are usually non-relativistic for white dwarfs and pulsars. For a supermassive black hole the velocities $\mathrm{v}_{\mathrm{i}}, \mathrm{v}_{\mathrm{m}}$ and $\mathrm{v}_{\mathrm{o}}$ may become relativistic, however, so that other terms may also contribute to the expression of $v_{\mathrm{m}}$ of (2.23). It is noticed that the frequencies $v_{\mathrm{i}}$ from (2.15), $v_{\mathrm{o}}$ from (2.16) and $v_{\mathrm{m}}$ from (2.23) have all been obtained by application of simple classical mechanics and Coulomb's law. Furthermore, none of these orbital frequencies depend on the rotational frequency $v_{\mathrm{s}}$ of the star. In section 5 of this work it will be shown how the influence of $v_{\mathrm{s}}$ may become manifest in another way.

In section 3 we will now discuss the interpretation of the gravitomagnetic field and the Lense-Thirring precession.

## 3. GRAVITOMAGNETIC FIELD AND LENSE-THIRRING PRECESSION

For the explanation of the low frequency QPOs of pulsars and black holes a special interpretation of the gravitomagnetic theory will be used. In this version, which may be deduced from general relativity [10-14], the so-called "magnetic-type" gravitational field is identified as a common magnetic field. Following this approach, the Lense-Thirring precession frequency and four new gravitomagnetic precession frequencies have recently been deduced [10]. The latter precession frequencies will shortly be discussed in section 4.

First, it is noticed, that our interpretation of the gravitomagnetic field leads to a prediction of the strength of the magnetic field of stars and black holes. Identification of the "magnetic-type" gravitational field with a magnetic field results into the so-called Wilson-Blackett formula. This relation applies, e.g., to a spherical star consisting of electrically neutral matter

$$
\begin{equation*}
\mathbf{M}(\mathrm{gm})=-1 / 2 \beta c^{-1} G^{1 / 2} \mathbf{S} . \tag{3.1}
\end{equation*}
$$

Here $\mathbf{M}(\mathrm{gm})$ is the gravitomagnetic dipole moment of the star with angular momentum $\mathbf{S}$, and $\beta$ is a dimensionless constant of order unity. Available observations and theoretical considerations with respect to the relation (3.1), and other explanations of the origin of the magnetic field of celestial bodies have been reviewed by Biemond [12]. The magnetic fields of pulsars have separately been discussed [13]. The angular momentum $\mathbf{S}$ for a spherical star with mass $m_{\mathrm{s}}$ and radius $r_{\mathrm{s}}$ can be calculated from the relations

$$
\begin{equation*}
\mathbf{S}=I \boldsymbol{\Omega}_{\mathrm{s}}, \text { or } S=I \Omega_{\mathrm{s}}=2 / 5 f_{\mathrm{s}} m_{\mathrm{s}} r_{\mathrm{s}}^{2} \Omega_{\mathrm{s}} \tag{3.2}
\end{equation*}
$$

where $\Omega_{\mathrm{s}}=2 \pi v_{\mathrm{s}}$ is the angular velocity of the star ( $v_{\mathrm{s}}$ is its rotational frequency), $I$ is the moment of inertia of the star and $f_{\mathrm{s}}$ is a dimensionless factor depending on the homogeneity of the mass density in the star (for a homogeneous mass density $f_{\mathrm{s}}=1$ ). For convenience sake, a value $f_{\mathrm{s}}=1$ will be assumed in this work.

Since no stellar radius $r_{\mathrm{s}}$ occurs in the Kerr or Kerr-Newman metric, equation (3.2) cannot be used for the calculation of the angular momentum $S$. The latter quantity, however, can be written as (see, e.g., Misner, Thorne and Wheeler [18])

$$
\begin{equation*}
S=c m_{\mathrm{s}} a \tag{3.3}
\end{equation*}
$$

where $a$ is the specific angular momentum. Note that the non-relativistic expression for the angular momentum $S$ of (3.2) contains the stellar radius $r_{\mathrm{s}}$, whereas $S$ in (3.3) depends on distance $a$. A special limiting case occurs, when $a$ is taken equal to $r_{\mathrm{g}}$. For $\mathrm{Sgr} \mathrm{A}^{*}$ combination of (1.1) and (3.3) then yields for $S$

$$
\begin{equation*}
\frac{a}{r_{\mathrm{g}}}=1 \rightarrow S=\frac{G m_{\mathrm{s}}^{2}}{c}=1.206 \times 10^{62} \mathrm{~g} \cdot \mathrm{~cm}^{2} \cdot \mathrm{~s}^{-1} \tag{3.4}
\end{equation*}
$$

It is noticed that for the choices $a=r_{\mathrm{g}}$ and $Q_{\mathrm{s}}=0$, i.e., in the extreme Kerr space-time, both event horizons $r_{-}$and $r_{+}$from (1.4) reduce to $r_{\mathrm{g}}$, whereas for $a=r_{\mathrm{g}}, \vartheta=90^{\circ}$ and $Q_{\mathrm{s}}=0$ $r_{\text {out }}$ from (1.5) reduces to $2 r_{\mathrm{g}}$.

The value of a gravitomagnetic dipole moment $\mathbf{M}$ (or an electromagnetic dipole moment $\mathbf{M}$ ) can be calculated from

$$
\begin{equation*}
\mathbf{M}=1 / 2 R^{3} \mathbf{B}_{\mathrm{p}} \text {, or } M=1 / 2 R^{3} B_{\mathrm{p}} . \tag{3.5}
\end{equation*}
$$

Here $\mathbf{B}_{\mathrm{p}}$ is the magnetic induction field at, say, the north pole of the star at distance $R$ from the centre of the star to the field point where $\mathbf{B}_{\mathrm{p}}$ may be observed $\left(R \geq r_{\mathrm{s}}\right)$.

Combination of (3.1), (3.2) and (3.5) yields the following gravitomagnetic prediction for $\mathbf{B}_{p}$

$$
\begin{equation*}
\mathbf{B}_{\mathrm{p}}(\mathrm{gm})=-2 / 5 \beta c^{-1} G^{1 / 2} m_{\mathrm{s}} r_{\mathrm{s}}^{-1} \boldsymbol{\Omega}_{\mathrm{s}} . \tag{3.6}
\end{equation*}
$$

The minus sign reflects that the vectors $\mathbf{B}_{\mathrm{p}}(\mathrm{gm})$ and $\boldsymbol{\Omega}_{\mathrm{s}}$ possess opposite directions for $\beta=$ +1 . Neither the sign nor the value of $\beta$ follows from the gravitomagnetic theory. It is stressed that $\mathbf{B}_{\mathrm{p}}(\mathrm{gm})$ at distance $r_{\mathrm{s}}$ has been derived for an ideal gravitomagnetic dipole located at the centre of the star. For a homogeneous mass distribution in the star, however, the same result for $\mathbf{B}_{\mathrm{p}}(\mathrm{gm})$ can be deduced [22]. For $a=r_{\mathrm{g}}$ and $Q_{\mathrm{s}}{ }^{\prime}=0$ combination of (3.1), (3.3) and (3.5) yields the following expression for $B_{\mathrm{p}}(\mathrm{gm})$ at distance $R=r_{\mathrm{g}}$ from the centre of Sgr A*

$$
\begin{equation*}
B_{\mathrm{p}}(\mathrm{gm})=-\beta G^{1 / 2} m_{\mathrm{s}} r_{\mathrm{g}}^{-2}=-6.4 \times 10^{12} \beta \text { Gauss. } \tag{3.7}
\end{equation*}
$$

Note that for lower values of the angular momentum $S$ the absolute value of $B_{\mathrm{p}}(\mathrm{gm})$ becomes smaller. In sections 5 and 6.3 the result of (3.7) will further be discussed.

In addition, precession phenomena are another consequence of the gravitomagnetic theory. The theory predicts an angular precession velocity $\boldsymbol{\Omega}(\mathrm{gm})$ for an angular momentum $\mathbf{S}$ of a star or a torus. The following relation then applies to $\boldsymbol{\Omega}(\mathrm{gm})$

$$
\begin{equation*}
\frac{\mathrm{d} \mathbf{S}}{\mathrm{dt}}=\boldsymbol{\Omega}(\mathrm{gm}) \times \mathbf{S} . \tag{3.8}
\end{equation*}
$$

The angular precession velocity $\boldsymbol{\Omega}(\mathrm{gm})$ of $\mathbf{S}$ around direction of the field $\mathbf{B}$ from gravitomagnetic origin is given by $[10,12,14]$

$$
\begin{equation*}
\boldsymbol{\Omega}(\mathrm{gm})=-2 \beta^{-1} c^{-1} G^{1 / 2} \mathbf{B}, \tag{3.9}
\end{equation*}
$$

where the precession frequency $v(\mathrm{gm})$ is given by $\Omega(\mathrm{gm})=2 \pi v(\mathrm{gm})$.
As a first example, the precession of the angular momentum $\mathbf{S}_{\mathrm{m}}$ of a circular torus with total mass $m_{\mathrm{m}}$ in the gravitomagnetic field of the star with angular momentum $\mathbf{S}$ will be considered. According to (3.8), an angular precession velocity $\boldsymbol{\Omega}$ (gm) of the component $\mathbf{S}_{\mathrm{m}} \sin \delta_{\mathrm{m}}\left(\delta_{\mathrm{m}}\right.$ is the angle between the directions of $\mathbf{S}$ and $\left.\mathbf{S}_{\mathrm{m}}\right)$, perpendicular to $\mathbf{S}$, occurs around $\mathbf{S}$. An approximately equatorial orbit of the torus will be adopted (i.e., $\delta_{\mathrm{m}}$ is small). By substitution of the equatorial value of the gravitomagnetic field $\mathbf{B}_{\mathrm{eq}}(\mathrm{gm})$ $=-R^{-3} \mathbf{M}(\mathrm{gm})$ into (3.9) $\boldsymbol{\Omega}(\mathrm{gm})$ can then directly be found

$$
\begin{equation*}
\boldsymbol{\Omega}_{\mathrm{LT}}=-c^{-2} G R^{-3} \mathbf{S}, \text { or } v_{\mathrm{LT}}=-2 / 5 c^{-2} G m_{\mathrm{s}} v_{\mathrm{s}} r_{\mathrm{s}}^{2} R^{-3} . \tag{3.10}
\end{equation*}
$$

The precession of the torus with mass $m_{\mathrm{m}}$ is an example of the Lense-Thirring precession of an orbital. Thus, the obtained result for $\boldsymbol{\Omega}(\mathrm{gm})$ is denoted by $\boldsymbol{\Omega}_{\mathrm{LT}}$ and the corresponding Lense-Thirring frequency by $v_{\text {LT }}$. It is noted, that $\mathbf{B}_{\mathrm{eq}}(\mathrm{gm})$ is approximately constant, when $\delta_{\mathrm{m}}$ is small. Since $\mathbf{S}_{\mathrm{m}} \sin \delta_{\mathrm{m}}$ reduces to zero for $\delta_{\mathrm{m}}=0$, however, precession only occurs for $\delta_{\mathrm{m}}>0$. In addition, it is noticed, that an ideal gravitomagnetic dipole moment $\mathbf{M}(\mathrm{gm})$, located at the centre of the star has been adopted in the derivation of (3.10). It has been shown in ref. [22], however, that for a homogeneous mass distribution in the sphere the equatorial value of the gravitomagnetic field $\mathbf{B}_{\text {eq }}(\mathrm{gm})$ at distance $R=r_{\mathrm{s}}$ may reduce to zero value. Then, according to (3.9), $\boldsymbol{\Omega}(\mathrm{gm})=\boldsymbol{\Omega}_{\mathrm{LT}}$ will also reduce to zero.

For $\delta_{\mathrm{m}}=90^{\circ}$ the gravitomagnetic field $\mathbf{B}$ in (3.9) is no constant and $\mathbf{B}$ has to be integrated over the whole orbit. An averaged result for the Lense-Thirring frequency $\bar{v}_{\mathrm{LT}}^{-}$ is then obtained for a circular orbit

$$
\begin{equation*}
\overline{\boldsymbol{\Omega}_{\mathrm{LT}}}=+2 c^{-2} G R^{-3} \mathbf{S}, \text { or } \overline{v_{\mathrm{LT}}}=4 / 5 c^{-2} G m_{\mathrm{s}} v_{\mathrm{s}} r_{\mathrm{s}}^{2} R^{-3} . \tag{3.11}
\end{equation*}
$$

Note that both in the derivation of (3.10) and (3.11) a gravitomagnetic field $\mathbf{B}$ has been substituted into (3.9). For both cases it makes no difference, whether the field $\mathbf{B}$ is identified as a magnetic induction field (we do so) or not. Another situation occurs, when an electromagnetic field $\mathbf{B}=\mathbf{B}(\mathrm{em})$ is substituted into (3.9). In section 4 we will consider examples of the latter alternative.

## 4. LOW FREQUENCY QUASI-PERIODIC OSCILLATIONS

If the field $\mathbf{B}$ in (3.9) may be identified with an electromagnetic field $\mathbf{B}(\mathrm{em})$, the following different gravitomagnetic precession frequencies can be distinguished (The adjective "gravitomagnetic" has been retained, since (3.9) describes the interaction
between some angular momentum and a magnetic field $\mathbf{B}$ ). Substitution into (3.9) of the field $\mathbf{B}(\mathrm{em})$ from the outer torus with total charge $Q_{0}$ and radius $r_{0}$, acting on the mass current with total mass $m_{\mathrm{m}}$, yields a precession frequency $v_{\mathrm{mo}}$. The following sequence with respect to the subscripts has been used: the first subscript m in $v_{\mathrm{mo}}$ stems from middle and the last subscript o from outer. The mass $m_{\mathrm{m}}$ in the torus with radius $r_{\mathrm{m}}$ in the middle experiences the action from the charge $Q_{o}$ in the outer torus ( $r_{\mathrm{o}}>r_{\mathrm{m}}$ ). Likewise, substitution into (3.9) of the field $\mathbf{B}(\mathrm{em})$ from the charge $Q_{\mathrm{i}}$ in the torus with radius $r_{\mathrm{i}}$, acting on mass $m_{\mathrm{m}}$, yields a frequency $v_{\mathrm{mi}}$. In addition, substitution of the field $\mathbf{B}(\mathrm{em})$ from charge $Q_{0}$, acting on the mass $m_{\mathrm{i}}$ in the torus with radius $r_{\mathrm{i}}$ and charge $Q_{\mathrm{i}}$, yields a frequency $v_{\mathrm{io}}$. Further, substitution of the field $\mathbf{B}(\mathrm{em})$ from charge $Q_{\mathrm{i}}$, acting on the mass $m_{\mathrm{o}}$ in the torus with radius $r_{\mathrm{o}}$ and charge $Q_{\mathrm{o}}$, yields a frequency $v_{\mathrm{o} i}$. Thus, four new precession frequencies are obtained.

The derivation of the four precession frequencies has been given in ref. [10, sections 3 and 4]. Here we only give the results and some additional remarks. As a first example, the precession frequency $v_{\mathrm{mo}}$ of the mass current with total mass $m_{\mathrm{m}}$, due to the total charge $Q_{\mathrm{o}}$ in the torus with radius $r_{\mathrm{o}}$, is given by

$$
\begin{equation*}
v_{\mathrm{mo}}=-Q_{\mathrm{o}}^{\prime} \frac{2 G m_{\mathrm{s}}}{c^{2} r_{\mathrm{o}}} v_{\mathrm{o}} g\left(x_{\mathrm{o}}\right) \cos \delta_{\mathrm{m}} \cos \delta_{\mathrm{o}} \tag{4.1}
\end{equation*}
$$

where $Q_{\mathrm{o}}{ }^{\prime}$ is again defined by $Q_{\mathrm{o}}{ }^{\prime} \equiv\left(G^{1 / 2} m_{\mathrm{s}}\right)^{-1} Q_{\mathrm{o}}$. The frequency of the charge $Q_{\mathrm{o}}$ in the torus with radius $r_{\mathrm{o}}$ is given by $v_{\mathrm{o}}$ (see (2.16)) and $x_{\mathrm{o}}$ is again defined by $x_{\mathrm{o}} \equiv r_{\mathrm{m}} / r_{\mathrm{o}}$. In addition, $\delta_{\mathrm{m}}$ and $\delta_{\mathrm{o}}$ are the angles between the direction of the rotation axis of the star $\mathbf{s}=$ $\boldsymbol{\Omega}_{\mathrm{s}} / \Omega_{\mathrm{s}}$ and the unit vectors $\mathbf{n}_{\mathrm{m}}$ and $\mathbf{n}_{\mathrm{o}}$ in the directions of the rotation axes of the tori with total mass $m_{\mathrm{m}}$ and total charge $Q_{\mathrm{o}}$, respectively. The minus sign in (4.1) means that the angular precession velocity $\boldsymbol{\Omega}_{\mathrm{mo}}\left(\Omega_{\mathrm{mo}}=2 \pi v_{\mathrm{mo}}\right)$ is counter-clockwise around $\mathbf{n}_{\mathrm{o}}$ for $\beta=$ +1 and a positive charge $Q_{0}$. The function $g\left(x_{0}\right)$ in (4.1) has been analogously defined to $g(x)$ in (2.19)

$$
\begin{equation*}
g\left(x_{\mathrm{o}}\right) \equiv \frac{2}{\pi}\left\{\frac{E\left(x_{\mathrm{o}}\right)}{\left(1-x_{\mathrm{o}}^{2}\right)}\right\} \tag{4.2}
\end{equation*}
$$

In addition, the charge $Q_{\mathrm{o}}$ in the outer torus with radius $r_{\mathrm{o}}$ acts on the mass $m_{\mathrm{i}}$ in the inner torus with radius $r_{\mathrm{i}}$ and may generate a precession frequency $v_{\mathrm{io}}$

$$
\begin{equation*}
v_{\mathrm{io}}=-Q_{\mathrm{o}}^{\prime} \frac{2 G m_{\mathrm{s}}}{c^{2} r_{\mathrm{o}}} v_{\mathrm{o}} g(x) \cos \delta_{\mathrm{i}} \cos \delta_{\mathrm{o}}, \tag{4.3}
\end{equation*}
$$

where $Q_{0}{ }^{\prime}, r_{\mathrm{o}}, v_{\mathrm{o}}$ and $\delta_{\mathrm{o}}$ are already given in (4.1) and $x$ is again defined by $x \equiv r_{\mathrm{i}} / r_{\mathrm{o}}$. In addition, $\delta_{\mathrm{i}}$ is the angle between the direction of the rotation axis of the star $\mathbf{s}=\boldsymbol{\Omega}_{\mathrm{s}} / \Omega_{\mathrm{s}}$ and the unit vector $\mathbf{n}_{\mathrm{i}}$ in the direction of the rotation axis of the torus with mass $m_{\mathrm{i}}$ and charge $Q_{i}$. Note that the quantity $g(x)$ in (4.3) equals to $g(x)$ in (2.19).

Furthermore, the precession frequency $v_{\mathrm{mi}}$ of the mass current with total mass $m_{\mathrm{m}}$, due to the total electric charge $Q_{\mathrm{i}}$ in the torus with radius $r_{\mathrm{i}}$, is given by

$$
\begin{equation*}
v_{\mathrm{mi}}=Q_{\mathrm{i}}^{\prime} \frac{2 G m_{\mathrm{s}}}{c^{2} r_{\mathrm{m}}} v_{\mathrm{i}} x_{\mathrm{i}} f\left(x_{\mathrm{i}}\right) \cos \delta_{\mathrm{m}} \cos \delta_{\mathrm{i}} \tag{4.4}
\end{equation*}
$$

where $Q_{\mathrm{i}}^{\prime}$ is again defined by $Q_{\mathrm{i}}^{\prime} \equiv\left(G^{1 / 2} m_{\mathrm{s}}\right)^{-1} Q_{\mathrm{i}}$. The frequency of the charge $Q_{\mathrm{i}}$ in the torus with radius $r_{\mathrm{i}}$ is given by $v_{\mathrm{i}}$ (see (2.15)) and $x_{\mathrm{i}}$ is again defined by $x_{\mathrm{i}} \equiv r_{\mathrm{i}} / r_{\mathrm{m}}$. The definitions of the angles $\delta_{\mathrm{m}}$ and $\delta_{\mathrm{i}}$ have already been given. The function $f\left(x_{\mathrm{i}}\right)$ has analogously been defined to $f(x)$ in (2.9)

$$
\begin{equation*}
f\left(x_{\mathrm{i}}\right)=\frac{-2}{\pi x_{\mathrm{i}}}\left\{K\left(x_{\mathrm{i}}\right)-\frac{E\left(x_{\mathrm{i}}\right)}{1-x_{\mathrm{i}}^{2}}\right\} . \tag{4.5}
\end{equation*}
$$

Finally, the charge $Q_{\mathrm{i}}$ in the inner torus with radius $r_{\mathrm{i}}$ acts on the mass $m_{\mathrm{o}}$ in the outer torus with radius $r_{\mathrm{o}}$ and may generate a precession frequency $v_{\mathrm{oi}}$

$$
\begin{equation*}
v_{\mathrm{oi}}=Q_{\mathrm{i}}^{\prime} \frac{2 G m_{\mathrm{s}}}{c^{2} r_{\mathrm{o}}} v_{\mathrm{i}} x f(x) \cos \delta_{\mathrm{i}} \cos \delta_{\mathrm{o}}, \tag{4.6}
\end{equation*}
$$

where all parameters have already been given before. The quantity $f(x)$ has earlier been defined in (2.9).

Note that the four frequencies $v_{\mathrm{io}}, v_{\mathrm{mo}}, v_{\mathrm{oi}}$ and $v_{\mathrm{mi}}$ contain the dimensionless quantity $G m_{\mathrm{s}} /\left(c^{2} r_{\mathrm{o}}\right)$ or $G m_{\mathrm{s}} /\left(c^{2} r_{\mathrm{m}}\right)$. In general, the quantity $G m_{\mathrm{s}} /\left(c^{2} r_{\mathrm{o}}\right)$ is smaller than unity value for white dwarfs, pulsars and black holes, so that the frequencies $v_{\text {mo }}$ and $v_{\text {io }}$ are usually smaller than $v_{0}$ and may therefore be denoted as low frequency QPOs. An analogous line of reasoning can be applied to the frequencies $v_{\mathrm{mi}}$ and $v_{\mathrm{oi}}$. Therefore, they can also be characterized as low frequency QPOs.

In addition, it is noticed that small angles $\delta_{\mathrm{m}}, \delta_{\mathrm{o}}$ and $\delta_{\mathrm{i}}$ have always been assumed in the derivations of the precession frequencies (4.1), (4.3), (4.4) and (4.6). If all values of $\delta$ nearly reduce to zero value, prograde motion of $Q_{\mathrm{i}}, m_{\mathrm{m}}$ and $Q_{\mathrm{o}}$ around $\mathbf{s}=\boldsymbol{\Omega}_{\mathrm{s}} / \Omega_{\mathrm{s}}$ takes place. Alternatively, retrograde motion of $Q_{\mathrm{i}}, m_{\mathrm{m}}$ and $Q_{\mathrm{o}}$ around s implies that all values of $\delta$ are about $180^{\circ}$.

Furthermore, a remark with respect to the relative magnitudes of $v_{\mathrm{mo}}$ and $v_{\mathrm{io}}$ can be made. Assuming $r_{\mathrm{i}}<r_{\mathrm{m}}<r_{\mathrm{o}}$, implies $x_{\mathrm{o}}>x$. According to table 1, the quantity $g\left(x_{\mathrm{o}}\right)$ is then larger than $g(x)$. When the angles $\delta_{\mathrm{m}}$ and $\delta_{\mathrm{i}}$ do not differ too much, it follows from (4.1) and (4.3) that the frequency $v_{\text {mo }}$ is larger than $v_{\text {io }}$. Finally, no sign of any of the frequencies $v_{\mathrm{i}}, v_{\mathrm{m}}, v_{\mathrm{o}}, v_{\mathrm{mo}}, v_{\mathrm{io}}, v_{\mathrm{mi}}$ and $v_{\mathrm{oi}}$ is known, at this moment. For that reason, positive signs for all frequencies will be used in the calculations below.

## 5. PARAMETER $\boldsymbol{\beta}^{*}$

When both a magnetic induction field $\mathbf{B}_{\mathrm{p}}(\mathrm{gm})$ from gravitomagnetic origin and a field $\mathbf{B}_{\mathrm{p}}(\mathrm{em})$ from electromagnetic origin are present at, say, the north pole of the pulsar, the total magnetic induction field $\mathbf{B}_{\mathrm{p}}($ tot $)$ is given by

$$
\begin{equation*}
\mathbf{B}_{\mathrm{p}}(\mathrm{tot})=\mathbf{B}_{\mathrm{p}}(\mathrm{gm})+\mathbf{B}_{\mathrm{p}}(\mathrm{em}) \tag{5.1}
\end{equation*}
$$

According to (3.6), the direction of $\mathbf{B}_{\mathrm{p}}(\mathrm{gm})$ is antiparallel to $\boldsymbol{\Omega}_{\mathrm{s}}$ for $\beta=+1$. It appears helpful to define the following dimensionless quantity $\beta^{*}$ (see ref. [13])

$$
\begin{equation*}
\mathbf{B}_{\mathrm{p}}^{\square}(\mathrm{tot})=\beta^{*} \mathbf{B}_{\mathrm{p}}(\mathrm{gm}) . \tag{5.2}
\end{equation*}
$$

When the total field $\mathbf{B}(\mathrm{tot})$ is from gravitomagnetic origin only, $\mathbf{B}_{\mathrm{p}}(\mathrm{em})=0$ and $\beta^{*}$ reduces to $\beta^{*}=1$. As a rule, measurements yield $B_{\mathrm{p}}(\mathrm{tot})$, so that only an estimate for $\beta^{*}$ can be obtained.

Several contributions to the field $\mathbf{B}_{\mathrm{p}}^{\|}(\mathrm{em})$ at the north pole of a star have been calculated in ref. [10]. First, a contribution $\mathbf{B}_{\mathrm{p}}^{\|}(\mathrm{em})=\mathbf{B}_{\mathrm{p}}^{\|}\left(Q_{\mathrm{s}}\right)$ is generated by the charge $Q_{\mathrm{s}}$ in the star with radius $r_{\mathrm{s}}$ and rotational frequency $v_{\mathrm{s}}$. A second contribution $\mathbf{B}_{\mathrm{p}}^{\|}(\mathrm{em})=$ $\mathbf{B}_{\mathrm{p}}^{\|}\left(Q_{\mathrm{i}}\right)$ is generated by the charge $Q_{\mathrm{i}}$ moving in the circular torus with radius $r_{1}$. A third contribution $\mathbf{B}_{\mathrm{p}}^{\|}\left(Q_{\mathrm{o}}\right)$ arises from charge $Q_{\mathrm{o}}$ moving in the circular torus with radius $r_{\mathrm{o}}$.

Combination of the gravitomagnetic contribution of (3.6) with these contributions to $\mathbf{B}_{\mathrm{p}}^{\|}(\mathrm{em})$ leads to the following expression for the parameter $\beta^{*}$ (see ref. [10])

$$
\begin{equation*}
\beta^{*}=1+\beta_{\text {current }}^{*}-Q_{\mathrm{s}}^{\prime}-5 / 2 Q_{\mathrm{i}}^{\prime} \frac{v_{\mathrm{i}}}{v_{\mathrm{s}}} \frac{r_{\mathrm{i}}^{2} / r_{\mathrm{s}}^{2} \cos \delta_{\mathrm{i}}}{\left(1+r_{\mathrm{i}}^{2} / r_{\mathrm{s}}^{2}\right)^{3 / 2}}-5 / 2 Q_{\mathrm{o}}^{\prime} \frac{v_{\mathrm{o}}}{v_{\mathrm{s}}} \frac{r_{\mathrm{o}}^{2} / r_{\mathrm{s}}^{2} \cos \delta_{0}}{\left(1+r_{\mathrm{o}}^{2} / r_{\mathrm{s}}^{2}\right)^{3 / 2}}, \tag{5.3}
\end{equation*}
$$

where $\delta_{\mathrm{i}}$ is the angle between the direction of the rotation axis $\mathbf{s}=\boldsymbol{\Omega}_{\mathrm{s}} / \Omega_{\mathrm{s}}$ of the star and the unit vector $\mathbf{n}_{\mathrm{i}}$, and so on. Quantities like $Q_{\mathrm{s}}{ }^{\prime}$ defined by $Q_{\mathrm{s}}{ }^{\prime} \equiv\left(G^{1 / 2} m_{s}\right)^{-1} Q_{s}$ have been defined earlier. Note that the terms in $Q_{\mathrm{s}}{ }^{\prime}, Q_{i}{ }^{\prime}$ and $Q_{\mathrm{o}}{ }^{\prime}$ are due to the contributions $\mathbf{B}_{\mathrm{p}}{ }^{\|}\left(Q_{\mathrm{s}}\right)$, $\mathbf{B}_{\mathrm{p}}^{\|}\left(Q_{\mathrm{i}}\right)$ and $\mathbf{B}_{\mathrm{p}}^{\|}\left(Q_{\mathrm{o}}\right)$, respectively. The term $\beta_{\text {current }}^{*}$ in (5.3) has been added to account for a possible contribution from toroidal currents in the star or black hole (see comment to (2.20)). For $\beta_{\text {current }}^{*}=-1$ toroidal currents completely compensate the magnetic field from gravitomagnetic origin. A striking property of (5.3) is that it provides a relation between the high frequency QPOs $v_{\mathrm{o}}$ and $v_{\mathrm{i}}$, and the rotation frequency $v_{\mathrm{s}}$ of the star. A related expression for $\beta^{*}$ was previously deduced [13] for a star with a flat disk.

Since no stellar radius $r_{s}$ has been defined for black holes, relation (5.3) cannot be applied in that case. A magnetic field $\mathbf{B}_{\mathrm{p}}$ (tot) at the poles of black holes is probably present, however. In order to obtain an estimate for $\beta^{*}$, $r_{\mathrm{s}}$ and $v_{\mathrm{s}}$ in (5.3) are replaced by $r_{\text {out }}$ from (1.5) for a chosen value of $a, \vartheta$ and $Q_{s^{\prime}}^{\prime}$, and by $v_{\mathrm{s}}=c /\left(2 \pi r_{\mathrm{out}}\right)$, respectively.

## 6. BLACK HOLES: THEORY AND OBSERVATIONS

In this section observations from the stellar black hole XTE J1550-564 and the supermassive black hole Sgr A* will be compared with predictions in previous sections. For that reason, the theoretical results will first be summarized.

### 6.1 Summary of theoretical results

The expressions for the frequencies $v_{\mathrm{i}}$ from (2.15) and $v_{\mathrm{o}}$ from (2.16) will only qualitatively be tested. In this work we will use the approximate relations (2.8) and (2.17)

$$
\begin{equation*}
Q_{\mathrm{s}} \approx x^{2} f(x) Q_{\mathrm{o}} \quad \text { and } \quad Q_{\mathrm{s}} \approx-g(x) Q_{\mathrm{i}}, \tag{6.1}
\end{equation*}
$$

where the quantity $x$ is defined by $x \equiv r_{\mathrm{i}} / r_{0}$. Instead of the quantities $f(x)$ and $g(x)$ in (6.1), the averaged values $f(\bar{x})=1 / 2\left\{f_{0}+f(x)\right\}=1 / 2\{0+f(x)\}=1 / 2 f(x)$ and $\bar{g}(\bar{x})=1 / 2\left\{g_{0}+g(x)\right\}$ (see section 2) will be used in the calculations below.

The high frequency QPO $v_{\mathrm{m}}$ has been given by (2.21)

$$
\begin{equation*}
v_{\mathrm{m}}=\frac{1}{2 \pi}\left(\frac{G m_{\mathrm{s}}}{r_{\mathrm{m}}^{3}}\right)^{1 / 2} \frac{1}{1+\frac{S}{c^{2} m_{\mathrm{s}}}\left(\frac{G m_{\mathrm{s}}}{r_{\mathrm{m}}^{3}}\right)^{1 / 2}}=\frac{1}{2 \pi}\left(\frac{G m_{\mathrm{s}}}{r_{\mathrm{m}}^{3}}\right)^{1 / 2} f_{\mathrm{s}} . \tag{6.2}
\end{equation*}
$$

This result applies for prograde motion of $d m_{\mathrm{m}}$ in the equatorial plane around a black hole. For white dwarfs and pulsars the relativistic factor $f_{\mathrm{S}}$ usually approaches unity, but for the black holes $f_{\mathrm{s}}$ may be smaller. When $S \rightarrow 0$, or $f_{\mathrm{s}} \rightarrow 1$, one can write

$$
\begin{equation*}
r_{\mathrm{K}}=\left\{\frac{G m_{\mathrm{s}}}{\left(2 \pi v_{\mathrm{m}}\right)^{2}}\right\}^{1 / 3} . \tag{6.3}
\end{equation*}
$$

An example of the more complicated relation (2.23) will be given in section 6.3.

The low frequency QPOs will be identified with the gravitomagnetic precession frequencies $v_{\mathrm{mo}}, v_{\mathrm{io}}, v_{\mathrm{mi}}$ and $v_{\mathrm{oi}}$ from (4.1), (4.3), (4.4) and (4.6) given by

$$
\begin{array}{ll}
v_{\mathrm{mo}}=-Q_{\mathrm{o}}^{\prime} \frac{2 G m_{\mathrm{s}}}{c^{2} r_{\mathrm{o}}} v_{\mathrm{o}} g\left(x_{\mathrm{o}}\right) \cos \delta_{\mathrm{m}} \cos \delta_{\mathrm{o}}, \quad x_{\mathrm{o}} \equiv r_{\mathrm{m}} / r_{\mathrm{o}}, \\
v_{\mathrm{io}}=-Q_{\mathrm{o}}^{\prime} \frac{2 G m_{\mathrm{s}}}{c^{2} r_{\mathrm{o}}} v_{\mathrm{o}} g(x) \cos \delta_{\mathrm{i}} \cos \delta_{\mathrm{o}}, \quad x \equiv r_{\mathrm{i}} / r_{\mathrm{o}}, \\
v_{\mathrm{mi}}=Q_{\mathrm{i}}^{\prime} \frac{2 G m_{\mathrm{s}}}{c^{2} r_{\mathrm{m}}} v_{\mathrm{i}} x_{\mathrm{i}} f\left(x_{\mathrm{i}}\right) \cos \delta_{\mathrm{m}} \cos \delta_{\mathrm{i}}, \quad x_{\mathrm{i}} \equiv r_{\mathrm{i}} / r_{\mathrm{m}}, \\
v_{\mathrm{oi}}=Q_{\mathrm{i}}^{\prime} \frac{2 G m_{\mathrm{s}}}{c^{2} r_{\mathrm{o}}} v_{\mathrm{i}} x f(x) \cos \delta_{\mathrm{i}} \cos \delta_{\mathrm{o}}, \quad x \equiv r_{\mathrm{i}} / r_{\mathrm{o}} . \tag{6.7}
\end{array}
$$

As an illustration, the precessing tori around the star with charge $Q_{\mathrm{i}}$, mass $m_{\mathrm{m}}$ and charge $Q_{0}$, respectively, are schematically given in figure 3 .

Figure 3. Rotation axes for a black hole or pulsar. The unit vector of the rotation axis of the star with charge $Q_{\mathrm{s}}$ (red) is $\mathbf{s} \equiv \boldsymbol{\Omega}_{\mathrm{s}} / \Omega_{\mathrm{s}}$. The unit vectors in the direction of the rotation axes of the circular tori with charge $Q_{\mathrm{i}}$ (blue), mass $m_{\mathrm{m}}$ (grey) and charge $Q_{\mathrm{o}}$ (red) are given by $\mathbf{n}_{\mathrm{i}}, \mathbf{n}_{\mathrm{m}}$ and $\mathbf{n}_{\mathrm{o}}$, respectively. The angle between $\mathbf{s}$ and $\mathbf{n}_{\mathrm{i}}$ is given by $\delta_{\mathrm{i}}$, and so on. The frequencies of the various tori are also denoted.

It is noticed that small angles $\delta_{\mathrm{m}}, \delta_{\mathrm{o}}$ and $\delta_{\mathrm{i}}$ (see figure 3) have been assumed in the derivations of the precession frequencies $v_{\mathrm{mo}}, v_{\mathrm{io}}, v_{\mathrm{mi}}$ and $v_{\mathrm{oi}}$. If all values of $\delta$ nearly reduce to zero value, prograde motion of $Q_{\mathrm{i}}, m_{\mathrm{m}}$ and $Q_{\mathrm{o}}$ around $\mathbf{s}=\boldsymbol{\Omega}_{\mathrm{s}} / \Omega_{\mathrm{s}}$ takes place. As a result of the precession processes, the angles $\delta\left(\delta_{\mathrm{o}}, \delta_{\mathrm{m}}\right.$ and $\left.\delta_{\mathrm{i}}\right)$ occurring in (6.4)-(6.7) vary in time. When the angles $\delta$ are small, however, they may approximately be treated as constants in the derivations of (5.3) and (6.4)-(6.7). Since all angles $\delta$ occur as $\cos \delta$ in these equations, the introduced errors are small in that case. Furthermore, it will be assumed that $r_{\mathrm{i}}<r_{\mathrm{m}}<r_{\mathrm{o}}$.

In favourable cases the mass $m_{\mathrm{s}}$, the radius $r_{\mathrm{s}}$ and seven frequencies (i.e., $v_{\mathrm{o}}, v_{\mathrm{m}}, v_{\mathrm{i}}$, $v_{\mathrm{mo}}, v_{\mathrm{i} \mathrm{o}}, v_{\mathrm{mi}}$ and $v_{\mathrm{oi}}$ ) are known. Nine unknown quantities are to be found (i.e., three charges: $Q_{\mathrm{s}}, Q_{\mathrm{o}}$ and $Q_{\mathrm{i}}$; three radii: $r_{\mathrm{o}}, r_{\mathrm{m}}$ and $r_{\mathrm{i}}$; three angles: $\delta_{\mathrm{o}}, \delta_{\mathrm{m}}$ and $\delta_{\mathrm{i}}$ ). Only the parameter $r_{\mathrm{K}}$ can directly be calculated from (6.3), when the frequency $v_{\mathrm{m}}$ can be assigned and when $v_{\mathrm{m}} \approx v_{\mathrm{k}}$. Only seven relations are available (i.e., two from (6.1), one from (6.3)
and four from (6.4)-(6.7)). Therefore, we have arbitrarily chosen one $\delta$ value, e.g., $\delta_{\mathrm{m}}$, and we have adopted $\delta_{\mathrm{i}}=\delta_{\mathrm{o}}$. Thus, choosing the value of two parameters, it appears possible to calculate the values of the remaining seven unknown quantities.

It is noted that by combining (6.1), (6.5) and (6.7) the following relation can be obtained, independent of $\cos \delta_{\mathrm{i}}, \cos \delta_{\mathrm{o}}, Q_{\mathrm{s}}, Q_{\mathrm{o}}$ and $Q_{\mathrm{i}}$

$$
\begin{equation*}
\frac{v_{\mathrm{io}} v_{\mathrm{i}}}{v_{\mathrm{oi}} v_{\mathrm{o}}}=\frac{g(x)^{2}}{x^{3} f(x)^{2}} \tag{6.8}
\end{equation*}
$$

It appears that all parameters $x, f(x)$ (or $f(\bar{x}))$ and $g(x)($ or $\bar{g}(\bar{x}))$ on the right hand side of (6.8) only depend on $x$. When all frequencies on the left hand side of (6.8) are known, all parameters on the right hand side can separately be calculated by an iteration process. In the calculations below use has been made of relation (6.8).

### 6.2 Stellar black hole XTE J1550-564

It is generally assumed that the binary system XTE J1550-564 contains a stellar black hole. As has previously been discussed [10], seven QPO frequencies may be extracted from observations (compare with a set of five QPO frequencies considered in ref. [8]). The seven QPO frequencies have been assigned to $v_{\mathrm{i}}, v_{\mathrm{m}}, v_{\mathrm{o}}, v_{\mathrm{mo}}, v_{\mathrm{io}}, v_{\mathrm{mi}}$ and $v_{\mathrm{oi}}$, respectively (see our table 2). Keeping in mind the assumption $r_{\mathrm{i}}<r_{\mathrm{m}}<r_{\mathrm{o}}$ in our model, the highest frequencies are attributed to $v_{\mathrm{i}}, v_{\mathrm{m}}$ and $v_{\mathrm{o}}$, respectively. An estimate of the relative magnitudes of the other four frequencies can often be made. For example, the frequency $v_{\mathrm{mo}}$ is usually larger than $v_{\mathrm{io}}$, as has been discussed in section 4 .

Introduction of the values $m_{\mathrm{s}}=9.61 m_{\odot}$ and $v_{\mathrm{m}}=v_{\mathrm{K}}=188 \mathrm{~Hz}$ (see table 2) for XTE $\mathrm{J} 1550-564$ into (6.3) yields for the Kepler radius $r_{\mathrm{K}}=9.706 \times 10^{6} \mathrm{~cm}=6.838 r_{\mathrm{g}}\left(r_{\mathrm{g}} \equiv\right.$ $G m_{\mathrm{s}} / c^{2}=1.419 \times 10^{6} \mathrm{~cm}$ ). In fact, we then assume a non-rotating black hole with angular momentum $S=0$, so that $f_{\mathrm{S}}=1$ (see (6.2)). Alternatively, the extreme value $S=c m_{\mathrm{s}} r_{\mathrm{g}}$ may be assumed for XTE J1550-564, resulting into

$$
\begin{equation*}
S=c m_{\mathrm{s}} a=c m_{\mathrm{s}} r_{\mathrm{g}}=\frac{G m_{\mathrm{s}}^{2}}{c}=8.134 \times 10^{50} \mathrm{~g} . \mathrm{cm}^{2} \cdot \mathrm{~s}^{-1} . \tag{6.9}
\end{equation*}
$$

Substitution of the parameters $m_{\mathrm{s}}=9.61 m_{\odot}, v_{\mathrm{m}}=188 \mathrm{~Hz}$ and the extreme value $S$ from (6.9) into (6.2) yields $r_{\mathrm{m}}=9.340 \times 10^{6} \mathrm{~cm}=6.580 r_{\mathrm{g}}$ and $f_{\mathrm{S}}=0.7195$.

In addition, the parameters $x, f(\bar{x})$ ) and $\bar{g}(\bar{x})$ have been calculated from (6.8) by an iteration process (see comment to this relation). Precise values of these parameters have been given in table 2, since these quantities are often very sensitive to small mutual changes in their value. Of course, the real accuracy of these parameters is much more limited. Note that the parameters $x, f(\bar{x})$ and $\bar{g}(\bar{x})$, can be calculated from (6.8) without knowledge of the value of mass $m_{\mathrm{s}}$.

In the next step, frequencies $v_{\mathrm{i}}$ and $v_{\mathrm{o}}$ from table $2, m_{\mathrm{s}}$ and the calculated parameters $x, \bar{f}(\bar{x}), \bar{g}(\bar{x})$ are combined with equations (6.1), (6.4)-(6.7). In addition, a value for $\delta_{\mathrm{m}}=5^{\circ}$ and the approximation $\delta_{\mathrm{i}}=\delta_{\mathrm{o}}$ is chosen. By application of an additional iteration process, accurate fits could then be found between observed and calculated values of $v_{\mathrm{mo}}, v_{\mathrm{io}}, v_{\mathrm{mi}}$ and $v_{\mathrm{oi}}$. Precise values for the obtained parameters $x_{\mathrm{i}}, f\left(\bar{x}_{\mathrm{i}}\right), \bar{g}\left(\bar{x}_{\mathrm{i}}\right)$, $x_{\mathrm{o}}, f\left(\bar{x}_{\mathrm{o}}^{-}\right), \bar{g}\left(\bar{x}_{\mathrm{o}}^{\prime}\right), Q_{\mathrm{s}}{ }^{\prime}, Q_{\mathrm{o}}{ }^{\prime}, Q_{\mathrm{i}}{ }^{\prime}, r_{\mathrm{K}}, r_{\mathrm{m}}, \delta_{\mathrm{i}}, \delta_{\mathrm{m}}$ and $\delta_{\mathrm{o}}$ have been summarized in table 2 . It is stressed again that the real accuracy of all these parameters is much more limited, especially the $\delta$ values. Results for XTE J1550-564 given in ref. [10] are based on $r_{\mathrm{K}}$, but the results presented in table 2 are based on the value of $r_{\mathrm{m}}$. Note that the parameters $x$, $f(\bar{x}), \bar{g}(\bar{x}), x_{\mathrm{i}}, f\left(\bar{x}_{\mathrm{i}}\right), \bar{g}\left(\bar{x}_{\mathrm{i}}\right), x_{\mathrm{o}}, \vec{f}\left(\bar{x}_{\mathrm{o}}\right), \bar{g}\left(\bar{x}_{\mathrm{o}}\right)$ and $\delta$ are not affected by this change.

Table 2. QPO frequencies $v_{0}$ (so-called centroid frequencies), values of the half-width signal at half maximum $\Delta$, quality factors $Q$ defined by $Q \equiv v_{0} /(2 \Delta)$, integrated fractional r.m.s. amplitudes and calculated parameters for black hole XTE J1550-564. The calculated parameters are: relative radii ( $x, x_{\mathrm{o}}$ and $x_{\mathrm{i}}$ ), radii ( $r_{\mathrm{i}}, r_{\mathrm{m}}$ and $r_{\mathrm{o}}$ ), relative charges $Q_{\mathrm{s}}{ }^{\prime}, Q_{\mathrm{o}}{ }^{\prime}$ and $-Q_{\mathrm{i}}{ }^{\prime}\left(Q^{\prime}\right.$ is defined by $Q^{\prime} \equiv$ $\left.\left(G^{1 / 2} m_{\mathrm{s}}\right)^{-1} Q\right)$, factors $f(\bar{x}), \bar{g}(\bar{x}), f\left(\bar{x}_{\mathrm{i}}\right), \bar{g}\left(\bar{x}_{\mathrm{i}}\right), f\left(\bar{x}_{0}\right)$ and $\bar{g}\left(\bar{x}_{\mathrm{o}}\right)$ and angles $\delta_{\mathrm{i}}$ and $\delta_{0}$. See text for comment.

${ }^{\mathrm{a}}$ See ref. [10] and references therein. ${ }^{\mathrm{b}}$ Definitions of these quantities have been given in sections 2 and 4 .
Table 2 shows that the obtained values for $\delta_{\mathrm{i}}$ and $\delta_{\mathrm{o}}$ are not small. In the derivations of the expressions $v_{\mathrm{io}}$ and $v_{\mathrm{oi}}$, however, small values for $\delta_{\mathrm{i}}$ and $\delta_{\mathrm{o}}$ have been adopted. In addition, line charges $Q_{\mathrm{i}}$ and $Q_{\mathrm{o}}$ in two tori have been assumed. However, when the charges $Q_{\mathrm{i}}$ and $Q_{0}$ reside in an inner and outer belt, respectively, the system may be more stable. The belts could be compared with the observed inner and outer Van Allen radiation belts around the Earth. Thus, the results of table 2 may remain approximately valid.

Instead of the identifications of table 2, one might choose: $v_{\mathrm{i}}=268 \mathrm{~Hz}, v_{\mathrm{o}}=62.9$ $\mathrm{Hz}, v_{\mathrm{oi}}=5.04 \mathrm{~Hz}$ and $v_{\mathrm{io}}=0.73 \mathrm{~Hz}$. Substitution of these frequencies in the left hand side of (6.8), however, yields a result smaller than unity value, incompatible with the prediction of the right hand side. Therefore, this alternative choice must be rejected.

Since the values of the parameter $\beta^{*}$ and the rotation frequency $v_{\mathrm{s}}$ are unknown for XTE J1550-564, no value of $\beta_{\text {current }}^{*}$ for XTE J1550-564 can be calculated from (5.3). Furthermore, a stellar radius $r_{\mathrm{s}}$ has not been defined for a black hole, so that the LenseThirring precession frequency $v_{\text {LT }}$ from (3.10b) cannot be calculated. Combination of (3.10a), the angular momentum $S$ from (6.9) and radius $R=r_{\mathrm{i}}$ from table 2, however, yields $v_{\mathrm{LT}}\left(m_{\mathrm{i}}\right)=17.0 \mathrm{~Hz}$ for the Lense-Thirring precession frequency of the inner torus with mass $m_{\mathrm{i}}$. Since $S$ may be smaller than the extreme value $S=c m_{\mathrm{s}} r_{\mathrm{g}}$, this value for $v_{\mathrm{LT}}\left(m_{\mathrm{i}}\right)$ may also be smaller. Moreover, the equatorial value of the gravitomagnetic field $\mathbf{B}_{\mathrm{eq}}(\mathrm{gm})$ at distance $R=r_{\mathrm{i}}$ may be smaller than assumed, also resulting into a smaller value for $v_{\mathrm{LT}}\left(m_{\mathrm{i}}\right)$ (see comment to (3.10)).

It is noticed that the opposite sign of all charges of $Q_{\mathrm{s}}, Q_{\mathrm{i}}$ and $Q_{\mathrm{o}}$ given in table 2 is also compatible with the same set of parameters $x, r, \delta, f(\bar{x})$ and $\bar{g}(\bar{x})$ in that table.

Finally, it is noted that the Kepler radius of $7.66 \times 10^{6} \mathrm{~cm}=5.40 r_{\mathrm{g}}$ calculated from $v_{\mathrm{i}}$ is smaller than the innermost stable circular orbit in Schwarzschild space-time $r_{\text {ISco }}=6 r_{\mathrm{g}}$. For $a=0$ and $Q_{\mathrm{s}}{ }^{\prime}=0.1009$ in Reissner-Nordstrøm space-time, however, a value of $r_{\text {ISCo }}=$ $5.98 r_{\mathrm{g}}$ is obtained from (1.6), compatible with the value $r_{\mathrm{i}}=8.585 \times 10^{6} \mathrm{~cm}=6.05 r_{\mathrm{g}}$
deduced in ref. [10]. For $a=r_{\mathrm{g}}$ and $Q_{\mathrm{s}}{ }^{\prime}=0.0971$ in Kerr-Newman space-time, a stable circular orbit of radius $r_{\mathrm{i}}=8.262 \times 10^{6} \mathrm{~cm}=5.82 r_{\mathrm{g}}$ follows from (1.6) $(F>0)$. See table 2. No preference value for $a$ can be extracted for XTE J1550-564 from our model.

### 6.3 Galactic black hole Sgr A*

For the supermassive black hole Sgr A* in the Galactic Center Miyoshi et al. [2] detected radio emissions in 2004, using the Very Long Baseline Array (VLBA). From their analysis of the data they obtained seven different QPO periods. All these periods and the corresponding frequencies are summarized in our table 3. Previously, Aschenbach et al. [3] reported more than seven QPO frequencies from two X-ray flares of $\mathrm{Sgr} \mathrm{A}^{*}$, detected by Chandra in 2000 and by XMM-Newton in 2002. In addition, a number of QPO frequencies was covered by $I R$ measurements (see ref. [3, especially table 2]). A review of the observations of Sgr A* up to about of 2005 was given by Aschenbach [4]. He concluded, that recent measurements gave no confirmation for QPO frequencies higher than about 1.5 mHz . Since the results of Miyoshi et al. [2] are less ambiguous, these data are used in our calculations. As can be seen from our table 3, a set of seven QPO frequencies may be assigned to the frequencies $v_{\mathrm{i}}, v_{\mathrm{m}}, v_{\mathrm{o}}, v_{\mathrm{mo}}, v_{\mathrm{io}}, v_{\mathrm{mi}}$ and $v_{\mathrm{oi}}$.

For a non-rotating black hole the Kepler radius $r_{\mathrm{K}}$ can again be calculated from (6.3) by introduction of the value $m_{\mathrm{s}}=3.7 \times 10^{6} m_{\odot}$, reported by Ghez et al. [15], and the $V L B A$ value $v_{\mathrm{K}}=0.992 \mathrm{mHz}$. One obtains $r_{\mathrm{K}}=2.330 \times 10^{12} \mathrm{~cm}=4.263 r_{\mathrm{g}}$ (see also (1.1)). According to (6.2), in that case $S=0$ and $f_{\mathrm{S}}=1$. Alternatively, in extreme Kerr space-time substitution of the same value of $m_{\mathrm{s}}, v_{\mathrm{m}}=0.992 \mathrm{mHz}$ and the extreme value $S=c m_{\mathrm{s}} r_{\mathrm{g}}$ from (3.4) into (6.2) yields $r_{\mathrm{m}}=2.150 \times 10^{12} \mathrm{~cm}=3.933 r_{\mathrm{g}}$ and $f_{\mathrm{S}}=0.8864$.

Table 3. QPO periods $(P)$ and QPO frequencies ( $v$ ) of the supermassive black hole Sgr A* from Very Long Baseline Array observations. See caption of table 2 for further comment.

${ }^{\mathrm{a}}$ Ref. [2]. ${ }^{\mathrm{b}}$ Definitions of these quantities have been given in sections 2 and 4.
In addition, the parameters $x, f(\bar{x}))$ and $\bar{g}(\bar{x})$ can be calculated from (6.8) by the same method applied in section 6.2. In the next step, the frequency $v_{i}=1.29 \mathrm{mHz}$ from $V L B A$ observations, the frequency $v_{\mathrm{o}}=0.751 \mathrm{mHz}$ from X-ray flares (see table 3 ), $m_{\mathrm{s}}=$ $3.7 \times 10^{6} m_{\odot}$, and the calculated parameters $x, \bar{f}(\bar{x}), \bar{g}(\bar{x})$, are combined with equations (6.1), (6.4)-(6.7). In addition, a value for $\delta_{\mathrm{m}}=10^{\circ}$ and the approximation $\delta_{\mathrm{i}}=\delta_{\mathrm{o}}$ is chosen. By application of an iteration process, accurate fits could then be found between
observed VLBA values of $v_{\mathrm{mo}}=0.531 \mathrm{mHz}, v_{\mathrm{io}}=0.296 \mathrm{mHz}, v_{\mathrm{mi}}=0.130 \mathrm{mHz}, v_{\mathrm{oi}}=$ 0.0622 mHz and the corresponding calculated values. Precise values for the obtained parameters for $x_{\mathrm{i}}, f\left(\bar{x}_{\mathrm{i}}\right), \bar{g}\left(\bar{x}_{\mathrm{i}}\right), x_{\mathrm{o}}, f\left(\bar{x}_{\mathrm{o}}\right), \bar{g}\left(\bar{x}_{\mathrm{o}}^{-}\right), Q_{\mathrm{s}}{ }^{\prime}, Q_{\mathrm{o}}{ }^{\prime}, Q_{\mathrm{i}}{ }^{\prime}, r_{\mathrm{K}}, r_{\mathrm{m}}, \delta_{\mathrm{i}}, \delta_{\mathrm{m}}$ and $\delta_{\mathrm{o}}$ have been summarized in table 3. It is stressed again that the real accuracy of the parameters is much more limited. Results for Sgr A* presented in table 3 are based on the value of $r_{\mathrm{m}}$. When the calculations are based on the value of $r_{\mathrm{K}}$, however, the parameters $x, f(\bar{x}), \bar{g}(\bar{x}), x_{\mathrm{i}}$, $f\left(\bar{x}_{\mathrm{i}}\right), \bar{g}\left(\bar{x}_{\mathrm{i}}\right), x_{\mathrm{o}}, f\left(\bar{x}_{\mathrm{o}}^{-}\right), \bar{g}\left(\bar{x}_{\mathrm{o}}^{-}\right)$and $\delta$ do not change.

As an alternative for the assignments in table 3, one may try: $v_{\mathrm{i}}=1.29 \mathrm{mHz}, v_{0}=$ $0.751 \mathrm{mHz}, v_{\mathrm{oi}}=0.296 \mathrm{mHz}$ and $v_{\mathrm{io}}=0.0622 \mathrm{mHz}$. Substitution of these frequencies in the left hand side of (6.8), however, yields a result smaller than unity value, incompatible the prediction of the right hand side. Therefore, this alternative choice must be rejected.

Contrary to most pulsars, the velocity of a point charge in a circular orbit around the supermassive black hole like $\mathrm{Sgr} \mathrm{A}^{*}$ may closely approach the light velocity $c$. As an example, we will compare the velocity $v_{i}$ of a charge element $d Q_{i}$ of the inner torus with $c$. Choosing $v_{\mathrm{i}}=1.29 \mathrm{mHz}$ and $r_{\mathrm{i}}=1.959 \times 10^{12} \mathrm{~cm}=3.585 r_{\mathrm{g}}$ from relation $r_{\mathrm{i}}=x_{\mathrm{i}} r_{\mathrm{m}}$ (see table 3), one obtains

$$
\begin{equation*}
\frac{\mathrm{v}_{\mathrm{i}}}{c}=\frac{2 \pi v_{\mathrm{i}} r_{\mathrm{i}}}{c}=0.53 \tag{6.10}
\end{equation*}
$$

This result for $r_{\mathrm{i}}$ can also be compared with the corresponding Kepler radius $r_{\mathrm{K}}=$ $\left\{G m_{\mathrm{s}} /\left(2 \pi v_{\mathrm{i}}\right)^{2}\right\}^{1 / 3}=1.955 \times 10^{12} \mathrm{~cm}=3.578 r_{\mathrm{g}}$. The latter value suggests that the charge dependent contribution to the right hand side of (2.15) is rather small in this case (see also comment to (2.15)).

From $r_{\mathrm{K}}=2.330 \times 10^{12} \mathrm{~cm}=4.263 r_{\mathrm{g}}$ and relation $r_{\mathrm{i}}=x_{\mathrm{i}} r_{\mathrm{K}}$ it follows that $r_{\mathrm{i}}=$ $2.123 \times 10^{12} \mathrm{~cm}=3.885 \mathrm{r}_{\mathrm{g}}$. This value for $r_{\mathrm{i}}$ is incompatible with the innermost stable circular orbit $r_{\text {ISCO }}=5.85 r_{\mathrm{g}}$ in Reissner-Nordstrøm space-time, calculated from (1.6) for the values $a=0$ and $Q_{\mathrm{s}}{ }^{\prime}=0.3150$. Analogously, choosing a value $a=r_{\mathrm{g}}$, radius $r_{\mathrm{i}}$ can be calculated from $r_{\mathrm{m}}=2.150 \times 10^{12} \mathrm{~cm}=3.933 r_{\mathrm{g}}$, resulting into $r_{\mathrm{i}}=x_{\mathrm{i}} r_{\mathrm{m}}=1.959 \times 10^{12} \mathrm{~cm}=$ $3.585 r_{\mathrm{g}}$. From (1.6) follows that the circular orbit for $r_{\mathrm{i}}=3.585 r_{\mathrm{g}}, a=r_{\mathrm{g}}$ and $Q_{\mathrm{s}}{ }^{\prime}=0.2907$ is stable $(F>0)$. Moreover, assuming $r_{\mathrm{i}}=r_{\text {ISCO }}$, it appears possible to find a unique value for the ratio $a / r_{\mathrm{g}}$ by combination of the relations (1.6) for $F=0$, (6.2) and $r_{\mathrm{i}}=x_{\mathrm{i}} r_{\mathrm{m}}$. Application of the iteration process yields: $a / r_{\mathrm{g}}=+0.584$ for $r_{\mathrm{m}}=4.072 r_{\mathrm{g}}, r_{\mathrm{i}}=3.711 r_{\mathrm{g}}$ and $Q_{\mathrm{s}}{ }^{\prime}=0.3009$. The latter value of $r_{\mathrm{i}}$ can be compared with the equatorial radius $r_{\mathrm{out}}=$ $1.954 r_{\mathrm{g}}$ from (1.5) for $a=+0.584 r_{\mathrm{g}}, \vartheta=90^{\circ}$ and $Q_{\mathrm{s}}{ }^{\prime}=0.3009$.

Calculations above illustrate, that frequencies $v_{\mathrm{m}}$ obtained from (2.21) for a nonzero angular momentum $S$ differ from the Kepler frequency $v_{\mathrm{K}}$. Another modification of $v_{\mathrm{K}}$ occurs, when the gravitational attractions between the torus with mass $m_{\mathrm{m}}$ and masses $m_{\mathrm{i}}$ and $m_{\mathrm{o}}$ in the other tori are taken into account. Calculation shows, that the frequency $v_{\mathrm{m}}$ for a mass element $d m_{\mathrm{m}}$ in the torus with total mass $m_{\mathrm{m}}$ is then given by (2.23). Although the values for $f\left(\bar{x}_{\mathrm{o}}^{-}\right)$and $\bar{g}\left(\bar{x}_{\mathrm{i}}\right)$ have been calculated (see table 3), the values of the masses $m_{\mathrm{i}}, m_{\mathrm{m}}$ and $m_{\mathrm{o}}$ are not known. However, since $m_{\mathrm{i}}$ and $m_{\mathrm{o}}$ are probably much smaller than $m_{\mathrm{s}}$, the terms in (2.23) depending on $m_{\mathrm{i}}$ and $m_{\mathrm{o}}$ can be neglected and $v_{\mathrm{m}}$ reduces to the Kepler frequency $v_{\mathrm{K}}$.

As has been discussed in section 3, our interpretation of the gravitomagnetic field leads to a prediction of a magnetic field $B_{\mathrm{p}}(\mathrm{gm})$ at the poles of the black hole. For example, for the choices $a=r_{\mathrm{g}}, \vartheta=0^{\circ}$ and $Q_{\mathrm{s}}{ }^{\prime}=0$ (extreme Kerr space-time), one obtains $r_{\text {out }}=r_{\mathrm{g}}$ from (1.5) for the distance from the centre of the black hole to a pole. Assuming $\beta=+1$, a value $B_{\mathrm{p}}(\mathrm{gm})=-6.4 \times 10^{12} \mathrm{G}$ is found in (3.7). When the values $a=+0.584 r_{\mathrm{g}}$, $\vartheta=0^{\circ}$ and $Q_{\mathrm{s}}{ }^{\prime}=0.3009$ are substituted into (1.5), one finds $r_{\text {out }}=1.75 r_{\mathrm{g}}$ in the more general Kerr-Newman space-time. Assuming again $\beta=+1$, a value $B_{\mathrm{p}}(\mathrm{gm})=-6.9 \times 10^{11} \mathrm{G}$ can then be calculated from a combination of (3.1), (3.3), (3.5) and $R=r_{\text {out }}=1.75 r_{\mathrm{g}}$. No
reliable value for the total field $B_{\mathrm{p}}($ tot $)$ at the poles of the black hole from (5.1) is known, but the field of $\operatorname{Sgr} \mathrm{A}^{*}$ may be much lower than $B_{\mathrm{p}}(\mathrm{gm})$.

In order to deduce an estimate for the parameter $\beta^{*}$ in (5.3) for $\mathrm{Sgr} \mathrm{A}^{*}$, we will replace radius $r_{\mathrm{s}}$ by the equatorial radius $r_{\text {out }}=1.954 r_{\mathrm{g}}$ from (1.5) for $a=+0.584 r_{\mathrm{g}}, \vartheta=90^{\circ}$ and $Q_{\mathrm{s}}{ }^{\prime}=+0.3009$. For the values of $Q_{\mathrm{i}}{ }^{\prime}$ and $Q_{\mathrm{o}}{ }^{\prime}$, corresponding to $Q_{\mathrm{s}}{ }^{\prime}$, one finds: $Q_{\mathrm{i}}{ }^{\prime}=-$ 0.1516 and $Q_{\mathrm{o}}{ }^{\prime}=+0.4695$. In addition, we approximate $v_{\mathrm{s}}$ by $v_{\mathrm{s}}=c /\left(2 \pi r_{\text {out }}\right)=4.47 \mathrm{mHz}$ by utilizing the equatorial radius $r_{\text {out }}=1.954 r_{\mathrm{g}}$. Calculation then yields the following result for the parameter $\beta^{*}$ (see table 3 for additional parameters)

$$
\begin{equation*}
\beta^{*}=1+\beta_{\text {current }}^{*}-0.301\left(\text { from } Q_{\mathrm{s}}\right)+0.038\left(\text { from } Q_{\mathrm{i}}\right)-0.065\left(\text { from } Q_{\mathrm{o}}\right) \tag{6.11}
\end{equation*}
$$

Note that the contributions from the tori with charges $Q_{\mathrm{i}}$ and $Q_{\mathrm{o}}$ to $B_{\mathrm{p}}^{\|}($tot $)$are small and almost cancel.

As has previously been discussed [10], the parameter $\beta^{*}$ in (5.3) may be small for fast rotating pulsars. Assuming $\beta^{*} \approx 0$ for $\operatorname{Sgr} \mathrm{A}^{*}$ in (6.11), leads to the value $\beta_{\text {current }}^{*} \approx-$ 0.67. This result implies that toroidal currents may largely compensate the magnetic field from gravitomagnetic origin. Note that for the fast rotating pulsars XTE J1807-294, IGR J00291+5934 and SAX J1808.4-3658 comparable values for $\beta_{\text {current }}^{*}$ were found [10]: $-0.737,-0.563$ and -0.499 , respectively.

It is noticed that the opposite sign of all charges of $Q_{\mathrm{s}}, Q_{\mathrm{i}}$ and $Q_{\mathrm{o}}$ given in table 3 is compatible with the same set of parameters $x, r, \delta, f(\bar{x})$ and $\bar{g}(\bar{x})$ in those tables. The choice of the opposite the sign of all charges, however, leads to a value $\beta_{\text {current }}^{*} \approx-1.33$ for $\operatorname{Sgr} \mathrm{A}^{*}$.

Since no rotation frequency $v_{\mathrm{s}}$ is known for $\mathrm{Sgr} \mathrm{A}^{*}$ and no stellar radius $r_{\mathrm{s}}$ has been defined for a black hole, the Lense-Thirring precession frequency $v_{\mathrm{LT}}$ from (3.10b) cannot be calculated. Combination of (3.10a), the angular momentum $S$ for $a=0.584 r_{\mathrm{g}}$ from (3.3) and radius $R=r_{\mathrm{i}}=3.711 r_{\mathrm{g}}$, however, yields the result $v_{\mathrm{LT}}\left(m_{\mathrm{i}}\right)=0.100 \mathrm{mHz}$ for the Lense-Thirring precession of the inner torus with mass $m_{\mathrm{i}}$. Since the orbit of this torus is close to the equatorial radius $r_{\text {out }}=1.954 r_{\mathrm{g}}$, the magnetic dipole approximation for the black hole is no longer valid and the value of $v_{\mathrm{LT}}\left(m_{\mathrm{i}}\right)$ will become smaller (see ref. [22] and comment to (3.10)).

Finally, it is has been suggested by Ballantyne et al. [23] that Sgr A* may be a source protons with an energy of several TeV . The present model may explain their origin: the protons due to the charge $Q_{\mathrm{s}}$ may leave the black hole at the poles during expansion of the outer torus with charge $Q_{0}$. In addition, protons may escape at the equator from the outer torus. Compare with comment to equation (2.20).

## 7. MASS OF SGR $A^{*}$

In view of its importance with respect to this and other work the value of the mass of $\mathrm{Sgr} \mathrm{A}^{*}$ is considered more in detail in this section. From 17 proper-motion stars near the Galactic Center Ghez, Salim, Hornstein et al. [15] calculated a central mass of (3.7 $\pm$ $0.2) \times 10^{6} m_{\odot}$ for a distance $R_{0}=8 \mathrm{kpc}$. In addition, Ghez, Salim, Weinberg et al. [16] analyzed the Keplerian orbit of the short period star S0-2, and deduced a value of ( $4.1 \pm$ $0.6) \times 10^{6} m_{\odot}$ for the enclosed mass at distance $R_{0}=8.0 \pm 0.6 \mathrm{kpc}$ (both quoted uncertainties are $68 \%$ confidence values). Moreover, they concluded from complex models, that the extended mass distribution amounts to less than $3-4 \times 10^{5} m_{\odot}$ within 0.01 pc. Furthermore, Schödel, Merrit and Eckart [17] measured the proper motions of more than 6000 stars and deduced a best-fit black hole mass of $(3.6+0.2 /-0.4) \times 10^{6} m_{\odot}$. In this work, a value $m_{\mathrm{s}}=3.7 \times 10^{6} m_{\odot}$ for the supermassive black hole $\mathrm{Sgr} \mathrm{A}^{*}$ has been used.

In this section we derive new expressions for the effective mass $m_{s}$ (eff) of a black hole acting on a companion star of mass $m_{\mathrm{c}}\left(m_{\mathrm{c}} \ll m_{\mathrm{s}}\right)$, moving in a circular orbit around that black hole. It is assumed that an additional massive torus is present, also moving in a
circular orbit around the black hole. It appears that the calculated effective mass $m_{\mathrm{s}}$ (eff) depends on the mass and the orientation of the orbital plane of the torus. Two expressions are deduced: one for coinciding orbital planes of companion star and torus and one for perpendicular orbital planes. Results are qualitatively compared with the reported mass value for $\mathrm{Sgr} \mathrm{A}^{*}$, deduced from the orbit of the companion star $\mathrm{S} 0-2$.

More in detail, we first consider a binary system, consisting of a black hole with mass $m_{\mathrm{s}}$ and a companion star with mass $m_{\mathrm{c}}$, moving in a circular orbit of radius $r_{\mathrm{c}}$ around the black hole. In addition, an inner torus with radius $r_{\mathrm{i}}$ and mass $m_{\mathrm{i}}$ and an outer torus with radius $r_{0}$ and mass $m_{0}$ are assumed to move in a circular orbits around the same black hole. The unit rotation vector $\mathbf{n}_{\mathrm{c}}$ of the orbit of the companion star and the unit vectors $\mathbf{n}_{\mathrm{i}}$ and $\mathbf{n}_{\mathrm{o}}$ of the orbits of the tori with mass $m_{\mathrm{i}}$ and mass $m_{0}$, respectively, all coincide. This configuration will be denoted as system A .

Analogous to the calculation of the Coulomb forces of $\mathbf{F}_{\text {is }}$ of (2.7), $\mathbf{F}_{\text {oi }}$ of (2.17) (from ref. [10]) and $\mathbf{F}_{\text {io }}$ of (2.4), the Newtonian forces between black hole with mass $m_{\text {s }}$ and the star with mass $m_{\mathrm{c}}, \mathbf{F}_{\mathrm{cs}}$, between mass $m_{\mathrm{c}}$ and torus with mass $m_{\mathrm{i}}, \mathbf{F}_{\mathrm{ci}}$, and between mass $m_{\mathrm{c}}$ and torus with mass $m_{\mathrm{o}}, \mathbf{F}_{\mathrm{co}}$ can be calculated. One obtains for system A

$$
\begin{equation*}
\mathbf{F}_{\mathrm{cs}}=-\frac{G m_{\mathrm{c}} m_{\mathrm{s}}}{r_{\mathrm{c}}^{2}} \mathbf{i}_{\mathrm{c}}, \quad \mathbf{F}_{\mathrm{ci}}=-g\left(x_{\mathrm{i}}\right) \frac{G m_{\mathrm{c}} m_{\mathrm{i}}}{r_{\mathrm{c}}^{2}} \mathbf{i}_{\mathrm{i}} \quad \text { and } \quad \mathbf{F}_{\mathrm{co}}=f\left(x_{\mathrm{o}}\right) \frac{G m_{\mathrm{c}} m_{\mathrm{o}}}{r_{\mathrm{o}}^{2}} \mathbf{i}_{\mathrm{o}} \tag{7.1}
\end{equation*}
$$

where $x_{\mathrm{i}}$ is defined by $x_{\mathrm{i}} \equiv r_{\mathrm{i}} / r_{\mathrm{c}}$ and $x_{\mathrm{o}}$ by $x_{\mathrm{o}} \equiv r_{\mathrm{c}} / r_{\mathrm{o}}$. In addition, the unit vector $\mathbf{i}_{\mathrm{c}}$ is given by $\mathbf{i}_{c}=\mathbf{r}_{\mathrm{c}} /\left|\mathbf{r}_{\mathrm{c}}\right|$, and so on. The spherical coordinate $\theta$ between the unit vector $\mathbf{n}_{\mathrm{c}}$ and the orbital planes of both tori is $90^{\circ}$. In addition, the quantities $f\left(x_{\mathrm{o}}\right)$ and $g\left(x_{\mathrm{i}}\right)$ are analogously defined to (2.24). The total gravitational force, $\mathbf{F}_{\mathrm{cs}}($ tot $)$, acting on mass $m_{\mathrm{c}}$, is then given by

$$
\begin{equation*}
\mathbf{F}_{\mathrm{cs}}(\text { tot })=\mathbf{F}_{\mathrm{cs}}+\mathbf{F}_{\mathrm{ci}}+\mathbf{F}_{\mathrm{co}}=-\frac{G m_{\mathrm{c}} m_{\mathrm{s}}}{r_{\mathrm{c}}^{2}} \mathbf{i}_{\mathrm{c}}\left(1+g\left(x_{\mathrm{i}}\right) \frac{m_{\mathrm{i}}}{m_{\mathrm{s}}}-f\left(x_{\mathrm{o}}\right) x_{\mathrm{o}}^{2} \frac{m_{\mathrm{o}}}{m_{\mathrm{s}}}\right) \tag{7.2}
\end{equation*}
$$

Comparison of the forces $\mathbf{F}_{\mathrm{cs}}$ in (7.1) and $\mathbf{F}_{\mathrm{cs}}($ tot $)$ in (7.2) shows, that the companion star with mass $m_{\mathrm{c}}$ is subjected to the Newtonian force from an effective mass $m_{\mathrm{s}}{ }^{\|}$(eff) of magnitude

$$
\begin{equation*}
m_{\mathrm{s}}^{\|}(\mathrm{eff})=m_{\mathrm{s}}+g\left(x_{\mathrm{i}}\right) m_{\mathrm{i}}-x_{\mathrm{o}}^{2} f\left(x_{\mathrm{o}}\right) m_{\mathrm{o}}=m_{\mathrm{s}}+\Delta m^{\|} \tag{7.3}
\end{equation*}
$$

The superscript $\|$ has been added, since the directions of all unit rotation vectors $\mathbf{n}_{c}, \mathbf{n}_{\mathrm{i}}$ and $\mathbf{n}_{0}$ of the orbits of masses $m_{\mathrm{c}}, m_{\mathrm{i}}$, and $m_{0}$, respectively, coincide. Note that the value of $m_{\mathrm{s}}^{\|}$(eff) is enhanced by the torus with mass $m_{\mathrm{i}}$, whereas it is diminished by the torus with mass $m_{0}$ (see also table 1).

Two limiting cases of (7.3) will now be distinguished. First, when $m_{0}=0$ and $x_{\mathrm{i}}$ approaches to zero value, $g\left(x_{\mathrm{i}}\right)$ approaches to unity value (see table 1). In this case, $m_{\mathrm{s}}^{\|}(\mathrm{eff})$ approaches to the value $m_{\mathrm{s}}^{\|}(\mathrm{eff})=m_{\mathrm{s}}+m_{\mathrm{i}}$. Such a result must be expected, because the companion star is subjected to the gravitational attraction of the black hole mass $m_{\text {s }}$ plus mass $m_{\mathrm{i}}$. Secondly, when relations $x_{\mathrm{i}}=x_{\mathrm{o}} \equiv x$ and $m_{\mathrm{i}}=m_{\mathrm{o}} \equiv m$ apply, the following values for $\Delta m^{\|}$can be calculated from table 1

$$
\begin{align*}
& x=0.99670 \rightarrow \Delta m^{\|}=2.799 m, \quad x=0.94449 \rightarrow \Delta m^{\|}=1.893 m,  \tag{7.4}\\
& x=0.71543 \rightarrow \Delta m^{\|}=1.348 m, \quad x=0.49903 \rightarrow \Delta m^{\|}=1.159 m .
\end{align*}
$$

From (7.3) and (7.4) follows, that for, e.g., $x=0.99670$ the companion star is attracted by a total mass $m_{\mathrm{s}}+m$ enclosed by its orbit, plus an additional mass contribution of 1.799 m . This effect is caused by the short distances between the companion star and both tori.

Alternatively, an effective mass $m_{\mathrm{s}}{ }^{\perp}$ (eff) can be calculated for another configuration of the same components, denoted as system B. In this system the rotation unit vector $\mathbf{n}_{\mathrm{c}}$ of the orbit of the companion star with mass $m_{\mathrm{c}}$ is perpendicular to the coinciding unit rotation vectors $\mathbf{n}_{\mathrm{i}}$ and $\mathbf{n}_{\mathrm{o}}$ of the orbits of the tori with mass $m_{\mathrm{i}}$ and mass $m_{0}$, respectively. System B is schematically given in figure 4 .

Figure 4. Configuration of system B. The vector $\mathbf{n}_{\mathrm{c}}$ denotes the unit rotation vector perpendicular to the orbit of the companion star with mass $m_{\mathrm{c}}$. The unit rotation vectors $\mathbf{n}_{\mathrm{i}}$ and $\mathbf{n}_{\mathrm{o}}$ of the orbits of the tori with mass $m_{\mathrm{i}}$ and mass $m_{\mathrm{o}}$, respectively, coincide with the $z$ axis. The spherical coordinate $\theta$, the angle between $O P(O$ is the centre of the black hole and $P$ is the position of the companion star) and the vectors $\mathbf{n}_{\mathrm{i}}$ and $\mathbf{n}_{\mathrm{o}}$ is given by $\theta=0^{\circ}$. Point $Q$ (with $\theta=90^{\circ}$ ) is another position of the orbit of the companion star, discussed in the text. Note that in this derivation the unit vector $\mathbf{s} \equiv$ $\boldsymbol{\Omega}_{\mathrm{s}} / \Omega_{\mathrm{s}}$ along the rotation axis of the black hole with mass $m_{\mathrm{s}}$ star need not to be specified.

Using again the formalism of section 2, the total Newtonian force from black hole and both tori acting on the companion star can be calculated. The position $P$ of the latter star is characterized by the spherical coordinate $\theta=0^{\circ}$ (see figure 4). An expression for $m_{\mathrm{s}}{ }^{\perp}$ (eff), analogous to (7.3) can be found. Substitution of the quantities $g\left(x_{\mathrm{i}}\right)$ from (2.22) in ref. [10] and $f\left(x_{0}\right)$ from (2.12) in this work, respectively, yields the following expression for $m_{\mathrm{s}}{ }^{\perp}$ (eff)

$$
\begin{equation*}
m_{\mathrm{s}}^{\perp}(\mathrm{eff})=m_{\mathrm{s}}+\frac{m_{\mathrm{i}}}{\left(1+x_{\mathrm{i}}^{2}\right)^{3 / 2}}+\frac{x_{\mathrm{o}}^{3} m_{\mathrm{o}}}{\left(1+x_{\mathrm{o}}^{2}\right)^{3 / 2}}=m_{\mathrm{s}}+\Delta m^{\perp} \tag{7.5}
\end{equation*}
$$

where $x_{\mathrm{i}}$ is again defined by $x_{\mathrm{i}} \equiv r_{\mathrm{i}} / r_{\mathrm{c}}$ and $x_{\mathrm{o}}$ by $x_{\mathrm{o}} \equiv r_{\mathrm{c}} / r_{\mathrm{o}}$. Note that the value of $m_{\mathrm{s}}{ }^{\perp}$ (eff) in (7.5) increases by the contribution of both inner and outer torus.

When $m_{\mathrm{o}}=0$ and $x_{\mathrm{i}}$ approaches to zero value, $m_{\mathrm{s}}{ }^{\perp}(\mathrm{eff})$ also approaches to the limiting value $m_{\mathrm{s}}{ }^{\perp}(\mathrm{eff})=m_{\mathrm{s}}+m_{\mathrm{i}}$, equal to the result of (7.3) in the corresponding limiting case. Choosing $x_{\mathrm{i}}=x_{\mathrm{o}} \equiv x$ and $m_{\mathrm{i}}=m_{\mathrm{o}} \equiv m$ as a second limiting case, the following values for $\Delta m^{\perp}$ can be calculated from table 1

$$
\begin{array}{ll}
x=0.99670 \rightarrow \Delta m^{\perp}=0.707 m, & x=0.94449 \rightarrow \Delta m^{\perp}=0.708 m  \tag{7.6}\\
x=0.71543 \rightarrow \Delta m^{\perp}=0.735 m, & x=0.49903 \rightarrow \Delta m^{\perp}=0.805 m .
\end{array}
$$

The different values for $\Delta m^{\|}$from (7.4) and $\Delta m^{\perp}$ from (7.6) imply different values for the effective masses $m_{\mathrm{s}}{ }^{\|}$(eff) and $m_{\mathrm{s}}{ }^{\perp}$ (eff) (see (7.3) and (7.5), respectively). Thus, the orientation of a torus or disk will cause an anisotropy in the value of the effective mass $m_{s}$ (eff) of the black hole. A related anisotropy has been proposed by Schödel, Merrit and Eckart [17] in their analysis of proper motions of stars orbiting around Sgr A*. As shown above, when $m_{\mathrm{o}}=0$ and $x_{\mathrm{i}}$ approaches to zero value, both $m_{\mathrm{s}}$ (eff) and $m_{\mathrm{s}}{ }^{\perp}$ (eff) reduce to $m_{\mathrm{s}}$ plus $m_{\mathrm{i}}$. In this limiting case the effective mass $m_{\mathrm{s}}(\mathrm{eff})$ of the black hole is isotropic.

The results of (7.4) and (7.6) lead to another remarkable prediction. To that end, consider the circular orbit of the companion star in system B, as illustrated in figure 4. As an example, for an arbitrarily chosen value like $x=0.99670$, the latter star is subjected to an effective mass $m_{\mathrm{s}}{ }^{\perp}(\mathrm{eff})=m_{\mathrm{s}}+0.707 m$ (see (7.5) and (7.6)) in point $P$ and an effective mass $m_{s}^{\|}($eff $)=m_{s}+2.799 m$ (see (7.3) and (7.4)) in point $Q$ of its orbit (see figure 4). As a result, the initially circular orbit of the companion star around the black hole will become approximately elliptical with, e.g., Sgr A* located in the centre of the ellipse (not in a focal point!'). Note that the described effect does not occur for the configuration of system A. In the latter case the value of the effective mass $m_{s}(\mathrm{eff})$ is constant along the whole orbit of the companion star.

In order to compare the described new effect with observations, the companion star S0-2 orbiting around Sgr A* may be considered. Assuming an ellipsoidal, Keplerian orbit for the star S0-2, Ghez, Salim, Weinberg et al. [16]) indeed found a small tentative difference between the focal point of the star and the position of the black hole. Before more definite conclusions can be drawn, however, more data about mass value, orientation and location of a massive torus or disk should be known.

Considering system A and utilizing (7.3) and (7.4), an estimate for the effective mass $m_{s}^{\|}$(eff) of Sgr A* may be chosen. Assuming a Keplerian orbit of the star S0-2 with a semi-major axis of 0.005 pc , Ghez, Salim, Weinberg et al. [16]) found an enclosed, central mass of $4.1 \times 10^{6} m_{\odot}$ for $\mathrm{Sgr} \mathrm{A}^{*}$. In addition, they deduced an upper-bound on the extended mass of about $0.35 \times 10^{6} m_{\odot}$ within 0.01 pc . Identifying the black hole mass $4.1 \times 10^{6} m_{\odot}$ with $m_{s}^{\|}$(eff) and taking $2 m$ equal to $0.35 \times 10^{6} m_{\odot}$, one finds for the arbitrary value $x=0.99670$ from (7.4) that $\Delta m^{\|}=2.799 m=2.799 \times 1 / 2 \times 0.35 \times 10^{6} m_{\odot}=0.5 \times 10^{6} m_{\odot}$. Thus, when the orbital planes of S0-2 and both tori coincide, the black hole mass $m_{\mathrm{s}}$ becomes equal to $m_{s}=m_{s}^{\|}$(eff $)-\Delta m^{\|}=3.6 \times 10^{6} m_{\odot}$. Likewise, for the configuration of system B a value for $m_{\mathrm{s}}$ lower than $4.1 \times 10^{6} m_{\odot}$ can be calculated. By choosing again the value $x=0.99670$ and by averaging the values of $m_{s}^{\|}$(eff) and $m_{\mathrm{s}}{ }^{\perp}(\mathrm{eff})$ obtained by a combination of (7.3) through (7.6), an estimated value of $m_{\mathrm{s}}=3.8 \times 10^{6} m_{\odot}$ can be found. Summing up, mass nearby to the orbit of S0-2 leads to higher values of $m_{\mathrm{s}}{ }^{\|}$(eff) and $m_{\mathrm{s}}^{\perp}$ (eff) compared with $m_{\mathrm{s}}$. Thus, the estimate of $m_{\mathrm{s}}=3.7 \times 10^{6} m_{\odot}$ for Sgr A* used in our calculations may be a reasonable choice.

## 8. RADIAL ESCAPE OF CHARGE FROM A BLACK HOLE

In order to investigate the origin of jets, the radial motion of a small charge, say a proton, from a star/black hole will be considered. By using Coulomb's law and classical mechanics, it has been shown in sections (2.1) and (2.2), that an equilibrium is possible between a positive charge $Q_{\mathrm{s}}$ of, e.g., black hole, a negative charge $Q_{\mathrm{i}}$ in an inner torus and a positive charge $Q_{o}$ in an outer torus around the black hole. For convenience sake, both tori are assumed to lie in the same equatorial plane of the black hole (see equations (2.8), (2.17) and figure 5). The electric field from a black hole system consisting of charges $Q_{\mathrm{s}}, Q_{\mathrm{i}}$ and $Q_{\mathrm{o}}$ acting on a small charge $e$ will be described by the Coulomb force, but at short distances from the centre the electric interaction may be different. In this
section we show, that it is possible that a small mass $m$ with charge $e$, say a proton, may be at rest slightly outside the radius $r_{\text {out }}$ of (1.5) for the black hole with positive charge $Q_{\mathrm{s}}$.

For a small charge moving in a radial direction the relations $d \vartheta=d \varphi=0$ apply. The Kerr-Newman metric of (1.2) then reduces to

$$
\begin{equation*}
d s^{2}=\frac{\Delta-a^{2} \sin ^{2} \vartheta}{r^{2}+a^{2} \cos ^{2} \vartheta} c^{2} d t^{2}-\frac{r^{2}+a^{2} \cos ^{2} \vartheta}{\Delta} d r^{2} \tag{8.1}
\end{equation*}
$$

where $\Delta$ is again given by (1.3b). The equations of motion are given by (see, e.g., [21])

$$
\begin{equation*}
\frac{d^{2} x^{\mu}}{d s^{2}}+\Gamma_{\alpha \beta}^{\mu} \frac{d x^{\alpha}}{d s} \frac{d x^{\beta}}{d s}=\frac{e}{m c^{2}} F_{v}^{\mu} \frac{d x^{v}}{d s}, \tag{8.2}
\end{equation*}
$$

where all parameters have their usual meaning. For radial motion the relevant nonvanishing Christoffel components are

$$
\begin{align*}
\Gamma_{r r}^{r} & =r_{\mathrm{g}}\left\{\frac{a^{2} \cos ^{2} \vartheta-r^{2}+\left(a^{2} / r_{\mathrm{g}}\right) r \sin ^{2} \vartheta+Q_{\mathrm{s}}^{\prime 2} r_{\mathrm{g}} r}{\Delta\left(r^{2}+a^{2} \cos ^{2} \vartheta\right)}\right\},  \tag{8.3}\\
\Gamma_{t t}^{r} & =-r_{\mathrm{g}} \Delta\left\{\frac{a^{2} \cos ^{2} \vartheta-r^{2}+\left(a^{2} / r_{\mathrm{g}}\right) r \sin ^{2} \vartheta+Q_{\mathrm{s}}^{\prime 2} r_{\mathrm{g}} r}{\left(r^{2}+a^{2} \cos ^{2} \vartheta\right)^{3}}\right\} .
\end{align*}
$$

In addition, the only relevant non-vanishing component of the electromagnetic field tensor is given by

$$
\begin{equation*}
F_{t}^{r}=\frac{-G^{1 / 2} m_{\mathrm{s}} Q_{\mathrm{s}}^{\prime}\left(a^{2} \cos ^{2} \vartheta-r^{2}\right) \Delta}{\left(r^{2}+a^{2} \cos ^{2} \vartheta\right)^{3}} . \tag{8.4}
\end{equation*}
$$

Assuming that the radial velocity $d r / d t$ equals to zero value, combination of (8.1)-(8.4) yields the following relation

$$
\begin{gather*}
\left(r^{2}-2 r_{\mathrm{g}} r+a^{2} \cos ^{2} \vartheta+Q_{\mathrm{s}}^{\prime 2} r_{\mathrm{g}}^{2}\right)^{1 / 2} Q_{\mathrm{s}}^{\prime}\left(r^{2}-a^{2} \cos ^{2} \vartheta\right)= \\
\frac{G^{1 / 2} m}{e}\left\{r^{2}-a^{2} \cos ^{2} \vartheta-\left(a^{2} / r_{\mathrm{g}}\right) r \sin ^{2} \vartheta-Q_{\mathrm{s}}^{\prime 2} r_{\mathrm{g}} r\right\}\left(a^{2} \cos ^{2} \vartheta+r^{2}\right)^{1 / 2} \tag{8.5}
\end{gather*}
$$

Note that the quantity $G^{1 / 2} m / e$ is a very small dimensionless number (for a proton $G^{1 / 2} m / e=$ $+8.996 \times 10^{-19}$ ).

For the limiting case of the Reissner-Nordstrøm space-time (see, e.g., ref. [18]) the specific angular momentum $a$ is zero, so that the condition (8.5) simplifies to

$$
\begin{equation*}
\left(r^{2}-2 r_{\mathrm{g}} r+Q_{\mathrm{s}}^{\prime 2} r_{\mathrm{g}}^{2}\right)^{1 / 2}=\frac{G^{1 / 2} m}{e Q_{\mathrm{s}}^{\prime}} r\left\{1-Q_{\mathrm{s}}^{\prime 2}\left(r_{\mathrm{g}} / r\right)\right\} \tag{8.6}
\end{equation*}
$$

Note that relation (8.6) does not depend on $\vartheta$. The solution with the highest value for $r$ from (8.6) can be written in terms of $r=r_{\mathrm{g}}\left(1+\delta^{\prime}\right)$, where $\delta^{\prime}$ is approximately given by

$$
\begin{equation*}
\delta^{\prime}=\left(1-Q_{\mathrm{s}}^{\prime 2}\right)^{1 / 2}+\varepsilon^{2}\left(1-Q_{\mathrm{s}}^{\prime 2}\right)^{1 / 2}\left\{1-1 / 2 Q_{\mathrm{s}}^{\prime 2}+\left(1-Q_{\mathrm{s}}^{\prime 2}\right)^{1 / 2}\right\} \tag{8.7}
\end{equation*}
$$

Here $\varepsilon$ is defined by $\varepsilon \equiv G^{1 / 2} m /\left(e Q_{s}{ }^{\prime}\right)$. This value can be compared with the corresponding radii $r_{+}=r_{\text {out }}=r_{\mathrm{g}}(1+\delta)($ see (1.4) and (1.5) for $a=0)$, where

$$
\begin{equation*}
\delta=\left(1-Q_{\mathrm{s}}^{\prime 2}\right)^{1 / 2} \tag{8.8}
\end{equation*}
$$

As an example, for a value like $Q_{\mathrm{s}}{ }^{\prime}=0.3009$ for $\mathrm{Sgr} \mathrm{A}^{*}$ (see section 6.3) $\delta$ obtains the value $\delta=0.954$, so that $\delta^{\prime}$ is then slightly more positive than $\delta$ (see (8.7)). Since the term containing $\varepsilon^{2}$ in (8.7) is small, $\delta^{\prime}$ can be approximated by $\delta$. As a result, the equatorial radius $r_{\text {out }}$ reduces to $r_{\text {out }}=1.954 r_{\mathrm{g}}$. Note that the magnitude of $Q_{\mathrm{s}}{ }^{\prime}$ in relations (8.7) and (8.8) is only limited by $Q_{\mathrm{s}}{ }^{\prime 2} \leq 1$. Therefore, apart from this upper limit, no maximum follows for charge added to charge $Q_{\mathrm{s}}^{\prime}$ in (8.7) at radius of $r=r_{\mathrm{g}}\left(1+\delta^{\prime}\right)$. The values of $\delta^{\prime}$ and $\delta$, and the corresponding radii, however, do depend on the value of $Q_{s}{ }^{\prime}$.

Since the quantity $G^{1 / 2} m / e$ in (8.5) is so extremely small, the right hand side of (8.5) can generally be approximated by zero value. Assuming that $Q_{\mathrm{s}}{ }^{\prime}>0$ and $a^{2}-r^{2} \cos ^{2} \vartheta \neq 0$, the two solutions $r_{\text {in }}$ and $r_{\text {out }}$ of (1.5) for $r$ result. For this reason, these radii may be interpreted as two possible equilibrium locations for a small positive charge near the centre of the black hole. For a small value of $G^{1 / 2} m / e$, the condition of a radial velocity $d r / d t=0$ is thus equivalent to the condition $g_{t t}=0$, leading to the relations of (1.5).

For a proton located on the rotation axis $\mathbf{s}=\boldsymbol{\Omega}_{\mathrm{s}} / \Omega_{\mathrm{s}}$ of the black hole (i.e., $\vartheta=0$ ), two values for $r$ exist, where the proton may be at rest. From (1.4) and (1.5) then follow the radii $r_{-}=r_{\text {in }}=r_{\mathrm{g}}-\left(r_{\mathrm{g}}^{2}-a^{2}-Q_{\mathrm{s}}^{\prime 2} r_{\mathrm{g}}^{2}\right)^{1 / 2}$ and $r_{+}=r_{\text {out }}=r_{\mathrm{g}}+\left(r_{\mathrm{g}}^{2}-a^{2}-Q_{\mathrm{s}}^{\prime 2} r_{\mathrm{g}}^{2}\right)^{1 / 2}$.

Figure 5. Scheme of jet model for a black hole like Sgr A* with a shell of positive charge $Q_{\mathrm{s}}$ (red) and mass $m_{s}$. The unit vector along the rotation axis of the star is $\mathbf{s} \equiv \boldsymbol{\Omega}_{\mathrm{s}} / \Omega_{\mathrm{s}}$. The unit vectors perpendicular to the circular tori with negative charge $Q_{\mathrm{i}}$ (blue), mass $m_{\mathrm{m}}$ (grey) and charge $Q_{\mathrm{o}}$ (red) all coincide with unit vector $\mathbf{s}$. The frequencies of the various tori with charge $Q_{\mathrm{i}}$, mass $m_{\mathrm{m}}$ and charge $Q_{\mathrm{o}}$ are denoted by $v_{\mathrm{i}}, v_{\mathrm{m}}$ and $v_{\mathrm{o}}$, respectively. It has been assumed that $r_{\mathrm{i}}=r_{\mathrm{ISCO}}$.

Another limiting case occurs at large distance from the centre of the black hole ( $r$ $\gg r_{\mathrm{g}}$ ). Then, combination of (8.1)-(8.4) yields the following non-relativistic result for the radial force

$$
\begin{equation*}
m \frac{d^{2} r}{d t^{2}}=-\frac{m G m_{\mathrm{s}}}{r^{2}}+\frac{e Q_{\mathrm{s}}}{r^{2}}=\frac{e Q_{\mathrm{s}}}{r^{2}}(1-\varepsilon) \tag{8.9}
\end{equation*}
$$

From this relation it follows that, e.g., a proton with mass $m$ and charge $e$ in presence of mass $m$ and a positive charge $Q_{\mathrm{s}}$ is attracted by the Newtonian force and repelled by the Coulomb force. For example, for $Q_{s}{ }^{\prime}=0.3009$ the quantity $\varepsilon$ is much smaller than unity value, so that the Coulomb force strongly dominates. It is noticed that for a system, consisting of a star with charge $Q_{\mathrm{s}}$ and two equatorial, charged tori with charges and $Q_{\mathrm{i}}$ and $Q_{0}$, a detailed expression for the electric field at the north pole of the star with radius $r_{\mathrm{s}}$ has previously been calculated [10]. Both expression (8.9) and the result of ref. [10], demonstrate the importance of Coulomb repulsion along the rotation axis of a black hole. As an illustration of our analysis figure 5 has been added.

Summing up, for a black hole with a positive relative charge $Q_{\mathrm{s}}{ }^{\prime}$ a proton with mass $m$ and charge $e$ is strongly repelled by the standard Coulomb force. For a non-rotating black hole $(a=0)$ and a value of $Q_{\mathrm{s}}{ }^{\prime}>0$, however, the proton may be at rest at distance $r$ slightly larger than $r_{\text {out }}=r_{\mathrm{g}}+r_{\mathrm{g}}\left(1-Q_{\mathrm{s}}{ }^{\prime 2}\right)^{1 / 2}$ from the centre of the black hole (compare (8.7) and (8.8)). For a fast rotating black hole, the proton may be at rest on the rotation axis of the black hole, at a distance $r$ slightly larger than $r_{\text {out }}=r_{\mathrm{g}}+\left(r_{\mathrm{g}}{ }^{2}-a^{2}-Q_{\mathrm{s}}{ }^{\prime 2} r_{\mathrm{g}}{ }^{2}\right)^{1 / 2}$ from the centre. Such a proton may combine with the large positive charge $Q_{\mathrm{s}}$.

More generally, the presented investigation of the radial motion of a small charge $e$ near a black hole, pulsar or other star with charge $Q_{\mathrm{s}}$ may give some key ingredients for the explanation of observed jets. At larger distances from the star a proton located on the rotation axis may be accelerated up to relativistic velocities by the Coulomb repulsion, for example, due to charge $Q_{\mathrm{s}}$, but at short distance from the centre the charge $Q_{\mathrm{s}}$ may be bound on a shell with radius given by $r_{\text {out }}$ of (1.5). When external charges $Q_{\mathrm{i}}$ and $Q_{\mathrm{o}}$ are present in two equatorial circular tori, an additional charge equilibrium may exist in the equatorial plane between the charges $Q_{\mathrm{s}}, Q_{\mathrm{i}}$ and $Q_{\mathrm{o}}$. Accretion may distort the latter charge equilibrium and may induce a charge burst mainly along the rotation axis of the star. See figure 5 as an illustration.

## 9. DISCUSSION OF THE THREE TORI MODEL

In this work three high frequency quasi-periodic oscillations (QPOs) of the black holes Sgr A* and XTE J1550-564 are attributed to three different circular tori: an inner torus with charge $Q_{\mathrm{i}}$, a torus with electrically neutral mass $m_{\mathrm{m}}$ and an outer torus with charge $Q_{\mathrm{o}}$. The corresponding QPO frequencies $v_{\mathrm{i}}, v_{\mathrm{m}}$ and $v_{\mathrm{o}}$ of the massive black hole Sgr A* and the stellar black hole XTE J1550-564 follow the sequence $v_{\mathrm{i}}>v_{\mathrm{m}}>v_{\mathrm{o}}$, whereas the values of the corresponding radii follow the sequence $r_{\mathrm{i}}<r_{\mathrm{m}}<r_{\mathrm{o}}$. The frequencies $v_{\mathrm{i}}, v_{\mathrm{m}}$ and $v_{\mathrm{o}}$, and the radii $r_{\mathrm{i}}, r_{\mathrm{m}}$ and $r_{\mathrm{o}}$ for these black holes are presented in section 6 and are summarized in table 4 . All radii, however, are now expressed in units of the gravitational radius $r_{g}$ of the considered black hole.

Generally spoken, the nature of the observed frequencies is "quasi-periodic". Thus, different measurements often yield slightly different values for the same QPO frequency, whereas one ore more QPO frequencies may be weak or even absent. For XTE J1550564 this problem has previously been discussed (see, e.g., [10]). For Sgr A* different values for the QPO periods/frequencies are reported by Miyoshi et al. [2] and Aschenbach et al. [3, 4]. In the future, more reliable QPO frequencies than summarized in table 3 may be observed for Sgr A*.

In addition, the identification of the various QPO frequencies is a major issue. As
an illustration, we compare the identification of the Kepler-like frequency $v_{\mathrm{m}}$ of (6.2) for XTE J1550-564 in some models. Stella and Vietra (see, e.g. ref. [5]), for example, attributed the highest observed QPO frequency $v_{\mathrm{u}}$ to $v_{\mathrm{m}}$ in their relativistic precession model. Schnittman and Bertschinger [8], however, motivated by the resonance model of Kluźniak and Abramowicz [6,7], analysed five observed QPO frequencies of XTE J1550-564 and attributed the second highest QPO frequency 276 Hz to $v_{\mathrm{m}}$ (corresponding to 268 Hz in our table 4). A resonance $v_{\mathrm{r}}: v_{\mathrm{m}}=1: 3$ was adopted in their analysis. Török [9], also following the model of refs. [6, 7], attributed the high QPO frequencies 276 Hz to $v_{\mathrm{u}}$ and 184 Hz to $v_{1}$, respectively, (corresponding to 268 Hz and 188 Hz in our table 4) for XTE J1550-564. Considering the resonance $v_{\mathrm{r}}: v_{\mathrm{m}}=1: 3$, in combination $v_{\mathrm{u}}=v_{\mathrm{m}}$ and $v_{\mathrm{l}}$ $=v_{\mathrm{m}}-v_{\mathrm{r}}$, yields the ratio $v_{\mathrm{u}} / v_{1}=2 / 3$ (in agreement with observations) and a value $a=+$ $0.43 r_{\mathrm{g}}$ for a mass $m_{\mathrm{s}}=9.61 m_{\odot}$. Additional resonances between $v_{\mathrm{r}}$ and $v_{\mathrm{m}}$ or $v_{\mathrm{v}}$ were discussed by Török [9], e.g., $v_{\mathrm{r}}: v_{\mathrm{m}}=1: 2$, in combination $v_{\mathrm{u}}=v_{\mathrm{m}}+v_{\mathrm{r}}=276 \mathrm{~Hz}$ and $v_{1}=v_{\mathrm{m}}$ $=184 \mathrm{~Hz}$, resulting into a theoretical ratio $v_{\mathrm{u}} / v_{\mathrm{l}}=3 / 2$ and a value $a=+0.29 \mathrm{r}$. Finally, in our three tori model for XTE J1550-564 we identify $v_{\mathrm{m}}$ with the second highest frequency of 188 Hz . From our three tori model, however, no value for $a$ follows.

For the supermassive black hole $\operatorname{Sgr} \mathrm{A}^{*}$ the identification of the Kepler-like frequency $v_{\mathrm{m}}$ is even more difficult. For example, Aschenbach et al. [3] gave an interpretation of four QPO frequencies in terms of the frequencies $v_{\mathrm{LT}}$ (our equation (3.11)), $v_{\mathrm{m}}, v_{\mathrm{v}}$ and $v_{\mathrm{r}}$. In their so-called low mass solution they attributed the extracted QPO frequency 4.562 mHz to $v_{\mathrm{m}}$, but later on Aschenbach [4] concluded, that more recent measurements gave no confirmation for QPO frequencies higher than about 1.5 mHz . Török [9] (compare with our table 3) only identified two QPO frequencies for Sgr A*: 1.445 mHz and 0.886 mHz with $v_{\mathrm{u}}$ and $v_{1}$, respectively. When a resonance $v_{\mathrm{r}}: v_{\mathrm{m}}=$ $1: 3$ is adopted, the combination $v_{\mathrm{u}}=v_{\mathrm{m}}$ and $v_{1}=v_{\mathrm{m}}-v_{\mathrm{r}}=0.886 \mathrm{mHz}$, then results into the ratio $v_{\mathrm{u}} / v_{\mathrm{l}}=3 / 2$ and a value 1.329 mHz for $v_{\mathrm{u}}$ (instead of the observed value 1.445 mHz ). In addition, a value $a=+0.86 r_{\mathrm{g}}$ then follows from the chosen mass $m_{\mathrm{s}}=3.7 \times 10^{6} m_{\odot}$. Alternatively, the choice $v_{\mathrm{r}}: v_{\mathrm{m}}=1: 2$, in combination with $v_{\mathrm{u}}=v_{\mathrm{m}}+v_{\mathrm{r}}$ and $v_{1}=v_{\mathrm{m}}=0.886$ mHz , leads again to the ratio $v_{\mathrm{u}} / v_{\mathrm{l}}=3 / 2$ and $v_{\mathrm{u}}=1.329 \mathrm{mHz}$, whereas $a$ changes into $a=$ $+0.84 r_{\mathrm{g}}$. For both considered resonances the theoretical ratio $v_{\mathrm{u}} / v_{1}=3 / 2$ differs from the observed ratio $v_{\mathrm{u}} / v_{\mathrm{l}}=1.63$. Finally, we have chosen $v_{\mathrm{m}}=0.992 \mathrm{mHz}$ from the reported data of Miyoshi et al. [2]. In conclusion, no QPO frequency for Sgr A* (or any other star!) has definitively been identified with the Kepler-like frequency $v_{\mathrm{m}}$.

Table 4. Summary of frequencies $v_{\mathrm{i}}, v_{\mathrm{m}}$ and $v_{\mathrm{o}}$ and radii $r_{\mathrm{i}}, r_{\mathrm{K}}, r_{\mathrm{m}}, r_{\mathrm{o}}$ and $r_{\text {ISCO }}$ (see tables 2 and 3) for the stellar black hole XTE J1550-564 and the massive black hole Sgr A*.

[^0]Table 4 shows that calculated radii $r_{\mathrm{i}}$ for XTE J1550-564 slightly differ from the value of the radius of the innermost stable circular orbit radius in Schwarzschild spacetime, $r_{\text {ISCO }}=6 \mathrm{Gm}_{\mathrm{s}} / c^{2}$. In Reissner-Nordstrøm space-time, a value of $r_{\text {ISCO }}=5.98 r_{\mathrm{g}}$ is obtained from (1.6) for $a=0$ and $Q_{\mathrm{s}}{ }^{\prime}=0.1009$, compatible with the value $r_{\mathrm{i}}=$ $8.585 \times 10^{6} \mathrm{~cm}=6.05 r_{\mathrm{g}}$ deduced in ref. [10]. For $a=r_{\mathrm{g}}$ and $Q_{\mathrm{s}}{ }^{\prime}=0.0971$ in Kerr-Newman space-time, a stable circular orbit of radius $r_{\mathrm{i}}=8.262 \times 10^{6} \mathrm{~cm}=5.82 r_{\mathrm{g}}$ follows from (1.6) $(F>0)$. For details see table 2 . No preference value for $a$ can be extracted for XTE J1550-564 from our three tori model.

For $\operatorname{Sgr} \mathrm{A}^{*}$ table 4 shows the calculated Kepler radius $r_{\mathrm{K}}=2.330 \times 10^{12} \mathrm{~cm}=$ $4.263 r_{\mathrm{g}}$ (see section 6.3) and radius $r_{\mathrm{i}}=2.123 \times 10^{12} \mathrm{~cm}=3.885 r_{\mathrm{g}}$ from relation $r_{\mathrm{i}}=x_{\mathrm{i}} r_{\mathrm{K}}$. Both radii are incompatible with the innermost stable circular orbit $r_{\text {ISCO }}=5.85 r_{\mathrm{g}}$ in Reissner-Nordstrøm space-time, calculated from (1.6) for $F=0, a=0$ and $Q_{\mathrm{s}}{ }^{\prime}=0.3150$. Alternatively, choosing value $a=r_{\mathrm{g}}$, radius $r_{\mathrm{i}}$ can be calculated from $r_{\mathrm{m}}=2.150 \times 10^{12} \mathrm{~cm}$ $=3.933 r_{\mathrm{g}}$, resulting into $r_{\mathrm{i}}=x_{\mathrm{i}} r_{\mathrm{m}}=0.91137 \times 2.150 \times 10^{12} \mathrm{~cm}=1.959 \times 10^{12} \mathrm{~cm}=3.585 r_{\mathrm{g}}$. From (1.6) follows that the circular orbit for $r_{\mathrm{i}}=3.585 r_{\mathrm{g}}, a=r_{\mathrm{g}}$ and $Q_{\mathrm{s}}{ }^{\prime}=0.2907$ is stable $(F>0)$. Assuming $r_{\mathrm{i}}=r_{\mathrm{ISCO}}$, it appears possible to find a unique value for the ratio $a / r_{\mathrm{g}}$ by combination of the relations (1.6) for $F=0$, (6.2) and $r_{\mathrm{i}}=x_{\mathrm{i}} r_{\mathrm{m}}$. Application of the iteration process yields: $a / r_{\mathrm{g}}=+0.584$ for $r_{\mathrm{m}}=4.072 r_{\mathrm{g}}, r_{\mathrm{i}}=3.711 r_{\mathrm{g}}$ and $Q_{\mathrm{s}}{ }^{\prime}=0.3009$. The latter value of $r_{\mathrm{i}}$ can be compared with the equatorial radius $r_{\text {out }}$ from (1.5). Substitution of $a=+0.584 r_{\mathrm{g}}, \vartheta=90^{\circ}$ and $Q_{\mathrm{s}}{ }^{\prime}=0.3009$ into (1.5) yields $r_{\text {out }}=1.954 r_{\mathrm{g}}$. In view of uncertainties in the extracted QPO frequencies and their assignments, however, the magnitude of $a$ for $\operatorname{Sgr} \mathrm{A}^{*}$ remains uncertain.

In table 5 the assigned low frequency QPOs $v_{\mathrm{mo}}, v_{\mathrm{io}}, v_{\mathrm{mi}}$ and $v_{\mathrm{oi}}$ from (6.4)-(6.7) for the black holes from tables 2 and 3 have been summarized. In addition, the relative charges $Q_{\mathrm{i}}{ }^{\prime}, Q_{\mathrm{o}}{ }^{\prime}$ and $Q_{\mathrm{s}}{ }^{\prime}\left(Q_{\mathrm{i}}{ }^{\prime}\right.$ is defined by $Q_{\mathrm{i}}{ }^{\prime} \equiv\left(G^{1 / 2} m_{\mathrm{s}}\right)^{-1} Q_{\mathrm{i}}$ and so on) have been added. It appears that the average value of the relative charges $Q_{s}{ }^{\prime}$ of both black holes amount to about 0.2 , whereas an average value of $Q_{s}{ }^{\prime}$ about 0.33 has previously been calculated for four pulsars [10].

Table 5. Summary of frequencies $v_{\mathrm{m} 0}, v_{\mathrm{io}}, v_{\mathrm{mi}}$ and $v_{\mathrm{oi}}$, relative charges $Q_{\mathrm{s}}{ }^{\prime}, Q_{\mathrm{i}}{ }^{\prime}$ and $Q_{\mathrm{o}}{ }^{\prime}$ from tables 2 and 3 for two black holes.

${ }^{\mathrm{a}}$ Used mass $m_{\mathrm{s}}=9.61 m_{\odot} \cdot{ }^{\mathrm{b}}$ Used mass $m_{\mathrm{s}}=3.7 \times 10^{6} m_{\odot}$.

For both black holes seven observed QPO frequencies in tables 4 and 5 have been identified with the seven predicted QPO frequencies of our model. The resonance model of Kluźniak and Abramowicz [6,7], only accounts for two QPO frequencies. In their analysis of the QPO frequencies of XTE J1550-564 by Schnittman and Bertschinger [8] the latter model has, however, been extended up to five QPO frequencies, the LenseThirring precession $\bar{v}_{\mathrm{LT}}^{--}$(our equation (3.11)) included. The relativistic precession model given by Stella, Vietri (see, e.g., [5]) only accounts for three basic QPO frequencies, when the Lense-Thirring precession frequency $\bar{v}_{\mathrm{LT}}^{--}$is included. Furthermore, Aschenbach et al. [3] gave an interpretation of four (or five) QPO frequencies for $\mathrm{Sgr} \mathrm{A}^{*}$ in terms of the frequencies $\bar{v}_{\mathrm{LT}}^{--}, v_{\mathrm{m}}, v_{\mathrm{v}}$ and $v_{\mathrm{r}}$.

Since the rotation frequency $v_{\mathrm{s}}$ is unknown and the stellar radius $r_{\mathrm{s}}$ has not been defined for black holes, the Lense-Thirring precession frequency $v_{\mathrm{LT}}$ of a torus cannot be calculated from (3.10b). Combination of (3.10a), the extreme value of the angular momentum $S$ from (3.3) and radius $R=r_{\mathrm{i}}$, however, yields a value for the Lense-Thirring precession $v_{\mathrm{LT}}\left(m_{\mathrm{i}}\right)$ of the inner torus with mass $m_{\mathrm{i}}$. Since the orbit of this torus is close to the black hole, the magnetic dipole approximation for the black hole may no longer be valid and the value of $v_{\mathrm{LT}}\left(m_{\mathrm{i}}\right)$ may become smaller (see ref. [22] and comment to (3.10)). Moreover, in our approach the gravitomagnetic field has been identified with a magnetic field. Calculated values for the Lense-Thirring frequencies $v_{\mathrm{LT}}\left(m_{\mathrm{i}}\right)$ for both black holes are given in sections 6.2 and 6.3. To my knowledge, however, no unambiguous identification of any Lense-Thirring frequency in any stellar system has yet been made.

## 10. CONCLUSIONS

A model with three circular tori has recently been proposed [10] in order to explain the quasi-periodic oscillations (QPOs) of pulsars, black holes and white dwarfs. Apart from the Lense-Thirring precession frequency $v_{\mathrm{LT}}$ (see equations (3.10) and (3.11), seven QPO frequencies are predicted in our model: three high frequency QPOs ( $v_{\mathrm{i}}, v_{\mathrm{m}}$ and $v_{\mathrm{o}}$ ) and four low frequency QPOs ( $v_{\mathrm{mo}}, v_{\mathrm{io}}$, $v_{\mathrm{mi}}$ and $v_{\mathrm{oi}}$ ). Details are given in sections 2 and 4 , and figure 3 is added as an illustration.

Reported QPO frequencies of the stellar black hole XTE J1550-564 and the supermassive black hole Sgr A* are compared with the seven QPO frequencies predicted by the new model. A good fit for both black holes could be found between observed and predicted frequencies, but two parameters had to be estimated. The results of most calculations are summarized in tables 4 and 5 and are compared with other models [4-9] in section 9. Moreover, for both black holes an estimate of the Lense-Thirring precession frequency $v_{L T}$ for an approximately equatorial orbit is given in section 6.

Summing up, the three tori model seems to be in agreement with more observations than previously proposed models. In view of the intermittent character of QPOs and uncertainty in their assignment, however, definite conclusions about the proposed model cannot yet be drawn.

In our analysis a precise value of the mass of $\mathrm{Sgr} \mathrm{A}^{*}$ is desirable. We shortly discussed available mass values [15-17] in section 7. The mass $m_{s}$ of $\mathrm{Sgr} \mathrm{A}^{*}$, for example, has been deduced from the orbit of star S0-2 around the black hole [16], so that enclosed mass within the orbit of SO-2 may contribute. In section 7 we deduce new expressions for the effective mass $m_{\mathrm{s}}$ (eff) of a black hole acting on a companion star of mass $m_{\mathrm{c}}\left(m_{\mathrm{c}} \ll m_{\mathrm{s}}\right)$, moving in a circular orbit around the black hole. It appears that the calculated effective mass $m_{\mathrm{s}}$ (eff) becomes larger than $m_{\mathrm{s}}$ by the presence of a massive torus in a circular orbit around the black hole. In addition, $m_{s}$ (eff) becomes anisoptropic: its value depends on the orientation of the orbital plane of the torus. Results are qualitatively compared with reported mass values for $\operatorname{Sgr} \mathrm{A}^{*}$. Moreover, the analysis reveals another peculiar effect, when the orbital planes of torus and companion star are perpendicular to each other. An initially circular orbit of the companion star around the black hole may become approximately elliptical with, e.g., Sgr A* located in the centre of the ellipse (not in a focal point!).

Finally, the origin of jets is considered in section 8. Starting from the KerrNewman metric, radial motion of a small mass $m$ with charge $e$, say a proton, near a black hole, pulsar or other star is investigated. It appears that a proton may be bound on a shell, slightly outside the outer radius $r_{\text {out }}$ of a black hole with (positive) charge $Q_{s}$. At larger distances from the centre of the black hole, however, protons can be accelerated up to relativistic velocities by the dominating Coulomb force. When external charges $Q_{\mathrm{i}}$ and $Q_{o}$ are present in two circular the tori in the equatorial plane, an additional charge equilibrium may exist between the charges $Q_{\mathrm{s}}, Q_{\mathrm{i}}$ and $Q_{\mathrm{o}}$. Accretion may distort the latter charge equilibrium and may induce a charge burst mainly along the rotation axis of the
star. Figure 5 is given as an illustration.

## ACKNOWLEDGEMENT

The technical help of my son Pieter in publishing this paper is gratefully acknowledged.
