# New prime k-tuple theorem (2) 

$P, P+j(j+1)(j=1, \cdots, k)$<br>Chun-Xuan Jiang<br>P. O. Box 3924, Beijing 100854, P. R. China<br>Jiangchunxuan@vip.sohu.com

#### Abstract

Using Jiang function we prove that for every positive integer $k$ there exist infinitely many primes $P$ such that each of $P+j(j+1)$ is prime.

## Theorem.

$$
\begin{equation*}
P, P+j(j+1)(j=1, \cdots, k) \tag{1}
\end{equation*}
$$

For every positive integer $k$ there exist infinitely many primes $P$ such that each of $P+j(j+1)$ is prime.
Proof. We have Jiang function [1, 2, 3]

$$
\begin{equation*}
J_{2}(\omega)=\prod_{P}[P-1-\chi(P)] \tag{2}
\end{equation*}
$$

where $\omega=\prod_{P} P$,
$\chi(P)$ is the number of solutions of congruence

$$
\begin{equation*}
\prod_{j=1}^{k}[q+j(j+1)] \equiv 0 \quad(\bmod P) \tag{3}
\end{equation*}
$$

where $q=1, \cdots, P-1$.
From (3) we have
If $P<2 k$ then $\chi(P)=\frac{P-1}{2}$, If $2 k<P$ then $\chi(P)=k$.
From (3) and (2) we have.

$$
\begin{equation*}
J_{2}(\omega)=\prod_{P=3}^{P<2 k} \frac{P-1}{2} \prod_{2 k<P}(P-1-k) \neq 0 \tag{4}
\end{equation*}
$$

We prove that for every positive integer $k$ there exist infinitely many primes $P$ such that each of $P+j(j+1)$ is prime.
We have the asymptotic formula [1, 2, 3]

$$
\begin{equation*}
\pi_{k+1}(N, 2)=\mid\{P \leq N: P+j(j+1)=\text { prime }\} \left\lvert\, \sim \frac{J_{2}(\omega) \omega^{k}}{\phi^{k+1}(\omega)} \frac{N}{\log ^{k+1} N}\right., \tag{5}
\end{equation*}
$$

where $\phi(\omega)=\prod_{P}(P-1)$.

Note Let $P=11,11+j(j+1)(j=1, \cdots, 9)$ are all prime.
Let $P=41,41+j(j+1)(j=1, \cdots, 39)$ are all prime.
Example 1. Let $k=1, P, P+2$, twin primes theorem.
From (4) we have

$$
\begin{equation*}
J_{2}(\omega)=\prod_{3 \leq P}(P-2) \neq 0 . \tag{6}
\end{equation*}
$$

We prove twin primes theorem. There exist infinitely many primes $P$ such that $P+2$ is prime.
From (5) we have the best asymptotic formula

$$
\begin{equation*}
\pi_{2}(N, 2) \sim 2 \prod_{3 \leq P}\left(1-\frac{1}{(P-1)^{2}}\right) \frac{N}{\log ^{2} N} . \tag{7}
\end{equation*}
$$

Exampe 2. Let $k=2, P, P+2, P+6$.
From (4) we have

$$
\begin{equation*}
J_{2}(\omega)=\prod_{5 \leq P}(P-3) \neq 0 . \tag{8}
\end{equation*}
$$

We prove that there exist intinitely many primes $P$ such that $P+2$ and $P+6$ are all prime.

From (5) we have the best asymptotic formula

$$
\begin{equation*}
\pi_{3}(N, 2) \sim \frac{9}{2} \prod_{5 \leq P} \frac{P^{2}(P-3)}{(P-1)^{3}} \frac{N}{\log ^{3} N} . \tag{9}
\end{equation*}
$$

Example 3. Let $k=6, P, P+j(j+1)(j=1, \cdots, 6)$
From (4) we have

$$
\begin{equation*}
J_{2}(\omega)=30 \prod_{13 \leq P}(P-7) \neq 0 . \tag{10}
\end{equation*}
$$

We prove that there exist infinitely many primes $P$ such that each of $P+j(j+1)$ is prime.
From (5) we have the best asymptotic formula

$$
\begin{equation*}
\pi_{7}(N, 2) \sim \frac{1}{16}\left(\frac{231}{48}\right)^{6} \prod_{13 \leq P} \frac{(P-7) P^{6}}{(P-1)^{7}} \frac{N}{\log ^{7} N} . \tag{11}
\end{equation*}
$$

Remark. Cramér's random model of prime theory is false.
Example. Assming that the events " $P$ is prime" and " $P+2$ and $P+4$ are primes" are independent, we conclude that $P, P+2$ and $P+4$ are simultaneously prime with probability about $1 / \log ^{3} N$. There are about $N / \log ^{3} N$ 3-tuple prime less than $N$. Letting $N \rightarrow \infty$ we obtain the 3-tuple conjecture which is false.
