Using Simple Number Theory to Predict Stable Isotopes

Sean C. Williams Herebe Ltd, Birkenhead, Wirral, UK E-mail: isotope@herebe.co.uk

Abstract

An abstract method is described for predicting stable isotopes using simple number theory based on a system of predefined combinations, or "Blocks", of protons and neutrons. Each Block is made up of a prime number of protons, and a binary power increase in the number of neutrons. Predictions using the Block system fully includes all the stable isotopes.

Introduction

The fundamental nature of matter has been at the forefront of scientific consideration from ancient time's right up until the present day [1]. A semi-empirical formula for binding energy using a summation of volume, surface, Coulomb repulsion and symmetry is taught to undergraduates in the Liquid Drop Model. This model "does not account for some of the finer details of nuclear process however, such as stability" [2, see p. 1448]. The Shell Model goes a long way towards describing stability, but as with the Liquid Drop Model, this is a literal interpretation of the atomic nucleus requiring the Coulomb force [2, see p. 1451].

Al Rabeh has published work on the relationship between prime numbers, geometry and physical structure [3] and this gives a clear insight in to the relationship between a solution based on abstract number theory and empirical evidence. This paper discusses the use of a purely abstract method for predicting stable isotopes using number theory.

In this paper, an isotope is only considered stable if it does not have a reported half life; so by this definition, Technetium, Promethium and Tungsten are not considered to have any stable isotopes [4].

Selection of number series

The series of stable isotopes can be predicted using a simple number theory based on a system of

predefined combinations, or Blocks, of protons and neutrons. Each Block is made up a prime number of protons, and a binary power increase in the number of neutrons. When researching this subject, several combinations of number series were considered, including simple multiplication, logarithmic powers, the Fibonacci series and the Magic Number series. A method for substituting prime numbers and binary powers by a combination of averaged Fibonacci series has also been considered.

It may well turn out that the use of alternative number series could give a better match for stable nuclei, however, the system of prime numbers and binary powers described in this paper reveals a regular pattern of instability in isotopes that are constructed using Block A — this has not been found when using other number series.

Application of the number series

Since all stable isotopes, with the exception of Hydrogen and Helium, contain an equal or greater number of neutrons than protons, the Blocks have been designed with positive integers. This means that, by design, the system cannot construct an isotope model with fewer neutrons than protons, although in reality these clearly exist. A model for all stable isotopes can be constructed from the following combination of protons and neutrons — referred to here as Blocks: The proton count increases by prime numbers and the neutron count increases by powers of two (binary powers).

Block	Р	Ν
А	1	1
В	2	2
С	3	4
D	5	8
E	7	16
F	11	32
etc		

Table 1: Block system using prime and binary power number series

Each isotope can be constructed using one or more of Blocks A, B, C, D, E, F, etc.; the only rule is that the largest Block available must be used. So, for example: Lithium-6 is created by combining one Block A (one proton and one neutron) and one Block B (two protons and two neutrons) = three protons and three neutrons. While Lithium-7 is created using a single Block C (three protons and four neutrons). Similarly, Neon-20 can be created using five units of Block B, whereas Neon-21 is created using three units of Block B and one of Block C. See Table 2: Applying the block system to isotopes:

Table 2: The combinations of blocks required to create isotopes between Lithium and Calcium.

Comments on Table 2:

Isotopes that cannot be calculated using the Block method have been omitted.

- Total Isotopes reported between Lithium and Calcium: 365 [4].
- Isotopes predicted as stable between Lithium and Calcium: 160.
- Actual stable Isotopes between Lithium and Calcium: 39.

This method produces a good percentage of stable isotopes up to Calcium, and it fares particularly well between Lithium and Neon. After Calcium, the number of models of isotopes that can be constructed using the proton/neutron Blocks expands, however so does the number of isotopes per element. The proton/neutron Block system still predicts the stable isotopes (it never misses a stable isotope) however, the number of unstable isotopes appearing within the models starts to increase and rapidly becomes greater than that of the stable isotopes.

Modifying the number series

It becomes clear that to predict the stable isotopes beyond Calcium, an additional factor, or modifier, must be used in number series for calculating the Blocks. The proton/neutron Blocks are not enough to discriminate between stable and un-stable isotopes, and so modifiers can be added as a triangulation device to further refine the predictions. These modifiers are built in to the Block system in exactly the same way as protons and neutrons. There are many different series that can be used here and as many modifiers can be added as desired (e.g. o setting a prime number sequence), however, a single modifier that works quite well up to Calcium is a simple Fibonacci series (dubbed

the "Abs" modifier) as in Table 3.

Block	Р	Ν	Abs
А	1	1	1
В	2 3	2 4	1
C	3	4	2
D	5	8	3
E	7	16	5
F	11	32	8
etc			

Table 3: Protons in prime numbers, neutrons in binary powers and Abs in Fibonacci series.

When plugging these figures in to the Block system, the results in Table 4 can be observed.

NB Isotopes that cannot be calculated using the Block method have been omitted.

What can be seen from Table 4 is that whilst the proton and neutron numbers increase in an orderly and predictable pattern, the Abs modifier does not. Removing isotopes so that the Abs modifier increases in an orderly and predictable fashion results in Table 5.

Table 5: Block system result using "orderly" Abs modifier.

Comments to the Table 5:

- Total Isotopes reported between Lithium and Calcium: 365 [4].
- Isotopes predicted as stable using Abs modifier between Lithium and Calcium: 71.
- Actual stable Isotopes between Lithium and Calcium: 39.

An interesting observation here is that it is the odd Z numbered elements that lose more isotopes when adjusting for the Abs modifier results in this way. When the Block sys-tem is applied to all the elements between Oxygen and Lead, it is revealed that there are no stable odd Z numbered elements that are built using Block A. This means that we can discount any isotope with an odd atomic number and we will find more stable isotopes in the elements with even atomic numbers which do not use Block A

Future work

The Block method has been used to predict the stability of isotopes up to Lead with similar results. Calculating the full periodic table, however, requires the use of further modifiers to cope with the range. It is hoped that further work will re-veal the closest match between predicted and observed stability. Close approximations can be made by replacing the prime and binary power number series with simple combinations of Fibonacci sequences.

An example for Tin is shown in Table 6. This uses a simple scoring mechanism of a summation of absolute values of the modifier scores to show approximate stability of each isotope. Tin is an interesting element because it contains a high proportion of stable isotopes. The values for the modifiers are calculated as the average score for all isotopes for a particular modifier using a specific number sequence. So in the example below, the proton sequence is prime numbers, the neutron sequence is binary powers, the Abs modifier sequence is 1, 2, 3, 5, 8, 13, 21 and the Hat modifier is 2, 3, 5, 8, 13, 21, 34.

The average value for the Abs modifier for all isotopes of Tin is 51 and for the Hat modifier is 80. These figures are then used for all values of Abs and Hat and the score is a sum of the absolute differences.

Figure 1: Plot of Score for Tin

Block Stability Prediction for Isotopes of Tin

Using this scoring method has the advantage of being able to make a prediction on all of the isotopes and so does not require the "orderly clean-up" method used in Table 5.

Summary

The Block system produces the following results:

• Actual stable isotopes between Lithium and Calcium: 39 out of 365 [4];

- When using the Block method with protons using a prime number series and neutrons using a binary power series, the isotopes predicted as stable between Lithium and Calcium is 160 out of 365;
- When using the Block method with protons using a prime number series, neutrons using a binary power series and introducing an Abs modifier using the Fibonacci series, the isotopes predicted as stable between Lithium and Calcium is 71 out of 365;
- Combinations of modifiers can be used to show regions of stability and it may be possible to find a combination of modifiers that offer an exact prediction of stable isotopes;
- Isotopes with odd Z numbers between Oxygen and Lead that are built using Block A are not be stable.
