#### Abstract

We introduce a law that we believe is a natural companion to the Biot-Savart Law of classical electrodynamics. The forces resulting from these two laws compliment one another: the force due to the Biot-Savart Law changes the direction of the velocity of a test particle, but not its magnitude; the force due to the companion law changes the magnitude of the velocity, but not its direction.

## 1 The Companion Law

The Biot-Savart law states that the element of magnetic field $d \mathbf{B}$ produced by a short segment $d \mathbf{l}$ of wire of arbitrary shape carrying a steady line current $I$, in SI units, is

$$
\begin{equation*}
d \mathbf{B}=\frac{\mu_{0}}{4 \pi} \frac{I d \mathbf{l} \times \hat{\mathbf{r}}}{r^{2}} \tag{1}
\end{equation*}
$$

with magnitude

$$
\begin{equation*}
|d \mathbf{B}|=d B=\frac{\mu_{0}}{4 \pi} \frac{I d l \sin \theta}{r^{2}} \tag{2}
\end{equation*}
$$

where $\theta$ is the angle between $\mathrm{d} \mathbf{l}$ and $\hat{\mathbf{r}}$.
I believe the Biot-Savart law has a companion law that, to my knowledge, has gone undiscovered until now. My companion laws to (1) and (2) introduce a 'scalar' field $H$ whose element $d H$ has similar form to (1) and (2). ${ }^{1}$

The companion law is derived from $\nabla \cdot \mathbf{A}$, where $\mathbf{A}$ is the vector potential due to a 'point' charge $q^{\prime}$ moving with constant velocity $\mathbf{v}^{\prime} .{ }^{2}$ We first note that $\mathbf{A}=\mathbf{v}^{\prime} \phi / c^{2}$, where $\phi=q^{\prime} /\left(4 \pi \epsilon_{0} r\right)$

[^0]is the scalar electric potential, due to $q^{\prime}$, at a field point $P$ a distance $r$ from $q^{\prime} .^{3}$ Thus, after substitution we get
\[

$$
\begin{equation*}
\nabla \cdot \mathbf{A}=\nabla \cdot\left(\frac{\mathbf{v}^{\prime} \phi}{c^{2}}\right)=-\frac{q^{\prime}}{4 \pi \epsilon_{0} c^{2}} \frac{\mathbf{v}^{\prime} \cdot \hat{\mathbf{r}}}{r^{2}} \tag{3}
\end{equation*}
$$

\]

where $\hat{\mathbf{r}}$ is a unit vector pointing from $q^{\prime}$ to $P$.
If we refer to $\nabla \cdot \mathbf{A}$ here as $H$, and note that $\epsilon_{0} \mu_{0}=1 / c^{2}$, we can write (3) as

$$
\begin{equation*}
H=-\frac{\mu_{0} q^{\prime}}{4 \pi} \frac{\mathbf{v}^{\prime} \cdot \hat{\mathbf{r}}}{r^{2}} \tag{4}
\end{equation*}
$$

Since $\mathbf{v}^{\prime} \cdot \hat{\mathbf{r}}$ is a scalar quantity (in three-dimensional space), we could also write (4) as

$$
\begin{equation*}
H=-\frac{\mu_{0} q^{\prime}}{4 \pi} \frac{v^{\prime} \cos \theta}{r^{2}} \tag{5}
\end{equation*}
$$

where $v^{\prime}$ is the magnitude of $\mathbf{v}^{\prime}$ and $\theta$ is the angle between $\mathbf{v}^{\prime}$ and $\hat{\mathbf{r}}$.
The element $d H$ at $P$ due to a 'point' charge $d q^{\prime}$ is

$$
\begin{equation*}
d H=-\frac{\mu_{0} d q^{\prime}}{4 \pi} \frac{\mathbf{v}^{\prime} \cdot \hat{\mathbf{r}}}{r^{2}} \tag{6}
\end{equation*}
$$

or

$$
\begin{equation*}
d H=-\frac{\mu_{0} d q^{\prime}}{4 \pi} \frac{v^{\prime} \cos \theta}{r^{2}} \tag{7}
\end{equation*}
$$

Now consider a small segment $d \mathbf{l}$ of wire carrying a steady current $I$, within which the 'point' charge $d q^{\prime}$ is moving with velocity $\mathbf{v}^{\prime}$ parallel to $d \mathbf{l}$. In terms of the current $I$, substituting $d q^{\prime}=I d t$ and $\mathbf{v}^{\prime}=d \mathbf{l} / d t,(6)$ and (7) become

$$
\begin{equation*}
d H=-\frac{\mu_{0}}{4 \pi} \frac{I d \mathbf{l} \cdot \hat{\mathbf{r}}}{r^{2}} \tag{8}
\end{equation*}
$$

or

$$
\begin{equation*}
d H=-\frac{\mu_{0}}{4 \pi} \frac{I d l \cos \theta}{r^{2}} \tag{9}
\end{equation*}
$$

where $d l$ is the magnitude of $d \mathbf{l}$. The equations (8) and (9) are my companions to (1) and (2), respectively.

We can find the total field $H$ at $P$ by integrating (8) along the wire, so that

$$
\begin{equation*}
H=-\frac{\mu_{0} I}{4 \pi} \int \frac{d \mathbf{l} \cdot \hat{\mathbf{r}}}{r^{2}} \tag{10}
\end{equation*}
$$

## 2 Force on a Test Charge in the Field $H$

The additional force $\mathbf{F}_{a}$ on a test charge $q$ at point $P$ moving with velocity $\mathbf{v}$ in the field $H$ at $P$ is ${ }^{4}$

$$
\begin{equation*}
\mathbf{F}_{a}=-q \mathbf{v} H \tag{11}
\end{equation*}
$$

[^1]If $H$ at $P$ is due to a 'point' charge $q^{\prime}$ moving with constant velocity $\mathbf{v}^{\prime}$, we can substitute (4) or (5) into (11), to obtain

$$
\begin{equation*}
\mathbf{F}_{a}=-q \mathbf{v}\left(-\frac{\mu_{0} q^{\prime}}{4 \pi} \frac{\mathbf{v}^{\prime} \cdot \hat{\mathbf{r}}}{r^{2}}\right)=\frac{\mu_{0} q q^{\prime}}{4 \pi} \frac{\mathbf{v}\left(\mathbf{v}^{\prime} \cdot \hat{\mathbf{r}}\right)}{r^{2}} \tag{12}
\end{equation*}
$$

or

$$
\begin{equation*}
\mathbf{F}_{a}=\frac{\mu_{0} q q^{\prime}}{4 \pi} \frac{\mathbf{v}\left(v^{\prime} \cos \theta\right)}{r^{2}} \tag{13}
\end{equation*}
$$

respectively.
For a steady line current $I$, the element of force $d \mathbf{F}_{a}$ on $q$ due to a short segment $d \mathbf{l}$ of wire, using (8), is

$$
\begin{equation*}
d \mathbf{F}_{a}=-q \mathbf{v} d H=\frac{\mu_{0} q \mathbf{v}}{4 \pi} \frac{I d \mathbf{l} \cdot \hat{\mathbf{r}}}{r^{2}} \tag{14}
\end{equation*}
$$

The total force $\mathbf{F}_{a}$ on $q$ can be found by integrating (14) along the wire, resulting in

$$
\begin{equation*}
\mathbf{F}_{a}=\frac{\mu_{0} q I \mathbf{v}}{4 \pi} \int \frac{d \mathbf{l} \cdot \hat{\mathbf{r}}}{r^{2}} \tag{15}
\end{equation*}
$$

It is interesting to note that the magnetic force $\mathbf{F}_{m}=q \mathbf{v} \times \mathbf{B}$ changes the direction of the velocity of a test particle, but not the magnitude of its velocity. In contrast, my additional force $\mathbf{F}_{a}=-q \mathbf{v} H$ changes the magnitude of the velocity, but not its direction. These two forces go hand-in-hand, along with the electric force $\mathbf{F}_{e}=q \mathbf{E}$, to complete the three-dimensional, non-relativistic equations of motion of a test particle. ${ }^{5}$

These equations predict new physics, but the most interesting prediction involves the time component of the force. Analyzing the time component of the force is outside of the threedimensional treatment here, however due to its implications I would like to mention it.

The time component of the force on $q$, due to $q^{\prime}$, is ${ }^{6}$

$$
\begin{equation*}
F_{t}=q\left(\frac{1}{c} \mathbf{v} \cdot \mathbf{E}+c \nabla \cdot \mathbf{A}\right) \tag{16}
\end{equation*}
$$

The last term is the time component of the additional force

$$
\begin{equation*}
F_{t a}=q c \nabla \cdot \mathbf{A} \tag{17}
\end{equation*}
$$

or

$$
\begin{equation*}
F_{t a}=q c H \tag{18}
\end{equation*}
$$

Substituting (4) into (18), we obtain

$$
\begin{equation*}
F_{t a}=-\frac{\mu_{0} q q^{\prime} c}{4 \pi} \frac{\mathbf{v}^{\prime} \cdot \hat{\mathbf{r}}}{r^{2}} \tag{19}
\end{equation*}
$$

For a steady line current $I$, using the same methods as above, we find that the element of force $d F_{t a}$ on $q$ due to a short segment $d \mathbf{l}$ of wire, is

$$
\begin{equation*}
d F_{t a}=-\frac{\mu_{0} q c}{4 \pi} \frac{I d \mathbf{l} \cdot \hat{\mathbf{r}}}{r^{2}} \tag{20}
\end{equation*}
$$

[^2]The total time component of the additional force $F_{t a}$ on $q$ can be found by integrating (20) along the wire, to obtain

$$
\begin{equation*}
F_{t a}=-\frac{\mu_{0} q c I}{4 \pi} \int \frac{d \mathbf{l} \cdot \hat{\mathbf{r}}}{r^{2}} \tag{21}
\end{equation*}
$$

If we extend Newton's Second Law $\mathbf{F}=m \mathbf{a}$ to include the time component of the force $F_{t}$, that is $F_{t}=m a_{t}$, where $a_{t}$ is the time component of the acceleration, then we can write the time component of the additional force as $F_{t a}=m a_{t a}$, where $a_{t a}$ is the acceleration due to the time component of the additional force $F_{t a} .^{7}$ Thus we can now write the time component of the acceleration $a_{t a}$ of $q$, due to $F_{t a}$, as

$$
\begin{equation*}
a_{t a}=-\frac{\mu_{0} q c I}{4 \pi m} \int \frac{d \mathbf{l} \cdot \hat{\mathbf{r}}}{r^{2}} \tag{22}
\end{equation*}
$$

where $m$ is the mass of $q$.
Note that $c$ in $F_{t a}$ and $d F_{t a}$ is the time component of the velocity of $q$, thus $q$ is stationary in space. ${ }^{8}$ Also note that, for a nonzero $F_{t a}\left(\right.$ or $\left.d F_{t a}\right)$, there is a nonzero acceleration in time. In other words, (22) describes a means of transporting $q$ in time.

[^3]
[^0]:    ${ }^{1}$ See http://www.softcom.net/users/der555/newtransform.pdf. The field $H$ is actually part of my generalized electric field (however, it is not referred to as $H$, there). Note that, here, I am using a three-dimensional, non-relativistic treatment, as opposed to the four-dimensional, relativistic treatment used at the above link.
    ${ }^{2} \nabla \cdot \mathbf{A}$ is physical and, in general, nonzero in my theory.

[^1]:    ${ }^{3}$ It is important to note that the scalar potential $\phi$, here, is the three-dimensional part of my four-dimensional potential at http://www.softcom.net/users/der555/newtransform.pdf, since this is a three-dimensional treatment.
    ${ }^{4}$ See http://www.softcom.net/users/der555/actreact.pdf.

[^2]:    ${ }^{5}$ See http://www.softcom.net/users/der555/actreact.pdf.
    ${ }^{6}$ See http://www.softcom.net/users/der555/actreact.pdf.

[^3]:    ${ }^{7}$ There are terms in addition to the time rate of change of four-momentum in my four-dimensional, relativistic treatment at http://www.softcom.net/users/der555/newtransform.pdf. These terms are considered to be relativistic, however, and are not considered here.
    ${ }^{8}$ I'm focusing, here, on the case where $q$ is stationary in $F_{t}$. There might also be an acceleration in time due to $(q / c) \mathbf{v} \cdot \mathbf{E}$ if $q$ is not stationary in space.
