Abstract.

The start of the 22-year cycle begins with a well-established dipole field component aligned along the solar rotational axis. The field lines tend to be held by the highly conductive solar plasma of the solar surface.

The solar dipole field, through similar processes, reverses again at the end of the 22-year cycle.

The new solar cycle by definition begins with the sun in the middle latitudes (around 30 ° north latitude and 30 degrees south latitude - Spörer's law) arises first sunspots. These spots have opposite magnetic polarity than the spots above the solar cycle.

Around the center of gravity of the Solar System $v_{\text{Sun}} = 377,64404380671797815401286112528 \text{ m/s}$

and $R_{\text{Sun orbit}} = 0,41727286425040580889702383164445e+11 \text{ m} = 0,27892571139733008616111218692781 \text{ AU.}$

Keywords: center of mass, angular momentum, solar cycle, orbit radius of the Sun around the center of gravity of the Solar System

Theory

According CONSEQUENCES 2 , points 15,16 and 17 p.63 [4] analogically we have:

Angular momentum simplified using the center of mass

It is very often convenient to consider the angular momentum of a collection of planets about their [center of mass](#), since this simplifies the mathematics considerably. The angular momentum of a collection of planets is the sum of the angular momentum of each planet:

$$\mathbf{L} = \sum_i \mathbf{R}_i \times m_i \mathbf{V}_i$$

where \mathbf{R}_i is the position vector of planet i from the reference point, m_i is its mass, and \mathbf{V}_i is its velocity. The center of mass is defined by:

$$\mathbf{R}_{\text{pl}} = \sum \mathbf{R}_{\text{pl}} * M_{\text{pi}} / \sum M_{\text{pi}}$$

$$11,391686777624717602881320381142e+11 = R_{\text{pl}} = \sum R_{\text{pl}} * M_{\text{pi}} / \sum M_{\text{pi}} = \sum R_{\text{pl}} * M_{\text{pi}} / 26,688295206e+26 \text{ kg}$$

$$\sum R_{\text{pl}} * M_{\text{pi}} = 11,391686777624717602881320381142e+11 * 26,688295206e+26 =$$

$$\sum R_{\text{pl}} * M_{\text{pi}} = 3,0402469961553533886808135451493e+39 \text{ kgm}$$

where the total mass of all planets is given by

$$M_p = \sum M_{\text{pi}}$$

It follows that the velocity of the center of mass of planet is

$$v_p = \sum v_{pi} * M_{pi} / \sum M_{pi}$$
