# cubic ellipsoid nucleus - atomic physics - part 1: the atomic radius 

Ronen Yavor
Abstract
This research explains and calculates the atomic radius and combines it with the ellipsoid nuclear model [17].
According to the ellipsoid nuclear model, the nucleus consists of nuclear shells that correlate with the atomic shells (unlike the common nuclear shell model); based on this assumption we get the following results:

- The protons have no effect on the electrons beyond their correlated atomic shell.
- Moreover possibly the protons only affect the electrons that correlate with their shell.
- A physical theoretical atomic radius function was constructed to meet these requirements.
- The nuclear structure determines the atomic shape and the electronic shielding; this explains the variation of the atomic radius from the calculated value and links between the nuclear and atomic structure.

## The model at a glance

According to the model these are the shape and properties of the nucleus:

- the nucleus has an ellipsoid shape.
- the nucleon bonds build a cubic system.
- protons are connected to neutrons (p-n).
- neutrons are connected mainly to protons.
- the protons are populated and organized in shells in the nucleus in analogy to those of the electrons in the atom.
- the energy layers (principal quantum number $\mathbf{n}$ ) grow with the distance from the origin.
- the perpendicular distance from the $\mathbf{z}$-axis in the $\mathbf{x}$ - $\mathbf{y}$-plane reflects the angular momentum (L, sub-orbitals).
- the upper half of the ellipsoid is referred to as spin-up and the lower part as spindown.
- the nucleus possibly rotates around its $\mathbf{z}$-axis.

The following drawings describe the idea via cross sections in the $\mathbf{x - z}$-plane of the nucleus.

1: a nucleon in the nucleus

2: the bonds between the nucleons

3: the energy levels of the nucleus

1. a nucleon (circle) is observed inside the ellipsoid (dashed line) that encloses the nucleons and schematically defines the nuclear surface:

- the distance from the origin represents its energy $\mathbf{E}$.
- the distance from the $\mathbf{z}$-axis depicts it angular momentum $\mathbb{L}$.
- the nucleons in the upper half have spin-up, and in the lower one spin-down.

2. the bonds between the nucleons are shown for visibility as springs.

- protons: full circles of the s, p and dl sub-orbitals. neutrons: hollow circles.

3. the circles of equal energy states $\mathbf{n}$ in the ellipsoid.

- the lines mark the development of the $\mathbf{s}, \mathrm{p}$ and dl sub-orbitals along the $\mathbf{z}$-axis.
- the $s$ line crosses all $\mathbf{n}$ circles from 1 to 4 ( $\mathbf{s} 1$ to $\mathbf{s 4}$ ).
- the p line begins by $\mathbf{n}=2$ and reaches till $\mathbf{n}=4$ (p2 to p4).
- the $\mathbf{d}$ line begins by $\mathbf{n}=3$ and reaches the ellipsoid border, before it reaches the $\mathbf{n}=4$ circle, and therefore there are no d4 states at this stage (only d3).

## Introduction

The following graph shows the experimental data of the (covalent single bond) atomic radius as a function of the atomic number.

atomic radius vs. atomic number $Z$ (Covalent single bond [2]); sub-orbitals: S, P, D, F

The atomic radius shows the following pattern:

- while moving from one row of the periodic table to the next one, the size of the atom grows.
- along a row of the periodic table the size of the atom shrinks.

In this research we try to explain and calculate these phenomena and connect it to the cubic ellipsoid nuclear model.

## The research

## Constructing the atomic radius function

We want to create a function for the atomic radius. The function should not only be adjusted mathematically, but of course also have a physical meaning.
The process we take is not precise, yet it seems to deliver results that are good enough for the assessment of the idea.
It is reminded here again that according to the model, the nuclear and atomic shells correspond to each other, and are as they appear in the periodic system.
Following definitions are used:

- $Z$ : the atomic number of the atom observed.
- $k \in\{1,2,3,4,5,6,7\}$ the current nuclear (and atomic) shell.
- $Z_{\text {shell }_{k}}$ : the number of protons (or electrons) currently in the shell, meaning:
- $Z_{\text {shell }_{k}}=Z-Z_{n . g_{k-1}}$.
- $Z_{n . g_{k-1}}$ : the (noble gas) atomic number that closes the last row of the periodic table.
- $r_{\text {shell }_{k}}$ : the atomic radius of the atom observed.

We estimate the force of the outermost nuclear shell on the outermost atomic shell.
Along a specific row (or shell) we suspect that the force that the nucleus acts on the electrons grows with the number of protons in the shell:

$$
F(Z) \sim Z_{\text {shell }_{k}}
$$

We also expect the following connection between the force and the radius:
$F \sim \frac{1}{r_{\text {shell }_{k}}^{2}}$ which leads to $r_{\text {shell }_{k}} \sim \frac{1}{\sqrt{F}}$ or $r_{\text {shell }_{k}} \sim \frac{1}{\sqrt{Z_{\text {shell }_{k}}}}$
and so $r_{\text {shell }_{k}}=\frac{a}{\sqrt{z_{\text {shell }_{k}}}}$
We thus try first the following simplified atomic radius formula:

$$
r(Z)=\frac{a}{\sqrt{z_{\text {seell }_{k}}}}+r_{\text {shell }_{k-1}}
$$

Remark: the function begins from the second row. for the first row we take the experimental data.
Testing the function produced the following values:

- $\quad r_{\text {shell }_{1}} \approx 30 \mathrm{pm}$ this is taken from the experimental data.
- $a \approx 90 \mathrm{pm}$ this is gained via trials.

## Analysis of the atomic radius function

The atomic radius function agrees well with the experiment. The variation seems to be mainly due to shielding effects, that are not taken directly into account in the function. The shielding is discussed in detail in the appendix.

graphs: experimental data of the covalent radius (S, P, D, F sub-orbitals); calculated atomic radius; radius of the last full shell

According to the atomic radius function, protons appear to have no effect on electrons beyond their correlated atomic shell; surprisingly it seems that also below their shells they have no influence.
We get to the conclusion, that according to this simplified model at least, each atomic shell is influenced only by its correlated nuclear shell.
The following illustration depicts this idea.

each nuclear shell affects only its corresponding atomic shell

## Discussion of the results and conclusions

The focus of this study is neither to define the precise atomic radius function, nor to find its exact parameters, but analyzing the mechanism that governs this process in the light of the cubic ellipsoid nuclear model.
Main statements of this research are:

- The atomic radius has the form $r \sim \frac{1}{\sqrt{Z_{\text {shell }}}}$ with:
$Z_{\text {shell }}$ the current number of protons (electrons) in the shell.
- The protons have no effect on the electrons beyond their correlated atomic shell.
- More precisely the protons possibly only affect the electrons that correlate with their shell.
- The nuclear structure determines the atomic shape and the amount of shielding that the field of the protons experiences; this explains the variation of the atomic radius from the calculated values and links between the nuclear and atomic structure.

These results seem to strengthen the ellipsoid nuclear model assumption that the shells of the nucleus and the atom correlate and that the structure of the nucleus determines the shape of the atom.
The model explains the growth of the atom while moving from one row of the periodic table to the next and the decreasing of the atomic radius along the shell itself.
In the appendix the graph of the atomic radius is discussed according to the atomic shells and orbitals.

## Appendix

## graphs

## Atomic radius - row 1

Only the $\mathrm{S}-1$ orbital is present and there is no shielding.
The radius values are taken from the experimental data.

## Atomic radius - row 2

The S-2 and P-2 orbitals are shielded almost equally by the S-1.
The radius values fit the experimental data.

## Atomic radius - row 3

The P-3 orbital is less shielded than the $\mathbf{S}-3$ one so we might expect it to be deeper than it really is.
The explanation might be that the total shielding is quite low and that the difference between the two orbitals is low too.

## Atomic radius - row 4

The D-3 lies deeper, because it is less shielded than the S-4 and the P-4 orbitals. The P-4 is less shielded than the S-4.

## Atomic radius - row 5

The D-4 is deeper, as it is less shielded than the S-5 and the P-5 orbitals.
The P-5 is less shielded than the $\mathrm{S}-5$.

## Atomic radius - row 6

The F-4 orbital is shielded and so lies somewhat around the curve.
The D-5 lies deeper, because it is less shielded than the others.
This possibly explains the lanthanide contraction.
The P-6 is less shielded than the S-6.

## data

the atomic radius function was defined as: $\quad r(Z)=\frac{a}{\sqrt{Z_{\text {shell }_{k}}}}+r_{\text {shell }_{k-1}}$
with:

- $Z$ : the atomic number of the atom observed.
- $\quad k \in\{1,2,3,4,5,6,7\}$ the current nuclear (and atomic) shell.
- $Z_{\text {shell }_{k}}$ : the number of protons (or electrons) currently in the shell, meaning:
- $Z_{\text {shell }_{k}}=Z-Z_{n . g_{k-1}}$.
- $Z_{n \cdot g_{k-1}}$ : the (noble gas) atomic number that closes the last row of the periodic table.
- $\quad r_{\text {shell }_{k}}$ : the atomic radius of the atom observed.
and the values:
- $r_{\text {shell }_{1}}=30 \mathrm{pm}$
- $a_{\text {row }} \approx 90 \mathrm{pm}$

The covalent radius in the table was taken from [2].
