

## Physics That Mandates a Vortex to Form

The physics that I'm about to describe to you is regarding the process that determines how a self generating vortex get it's initial rotation and in some cases continue under the same process. When the volume of water or gas that is involved in the formation of a vortex is unlimited, then the process will continue, but if the volume is of a relative small volume, as in a scientific lab, then the process or phase is over a short duration. This is why the scientific community has never noticed it. This process or phase is of a major importance to the scientific community. The universe is dictated by the properties of a vortex as in the formation of a galaxy, solar system, stars and planets. Knowing the actual basic physics of how a vortex function will have major importance in how the universe actually works.

I am going to start with a basin of water with a pipe leaving the center of the basin. The water that is entering the pipe has 100% of the gravitational force being applied to it. The gravitational force demands that this water to accelerate to terminal velocity. This 100% gravitational force of energy has to be deluded into the rest of the system in the basin, which will cause the water in the basin to accelerate at a different velocity. This has set up a dilemma, you have a fluid that cannot be compressed or stretch, but is required by the gravitational force to accelerate at two different velocities. This first sounds like this is impossible to accomplish, but can be solved easily. The 100% gravitational force water is required to accelerate to terminal velocity in a circular manner around the inner pipe, while at the same time, the water is sliding down the pipe at the accelerating velocity of the water that is in the basin. This phase of process will only be functional, if the volume of water or gas is based on infinity. When the water or gas is limited and the velocity of the circulating water in the basin equals the velocity of the circulating water going down the pipe, then the phase or process will collapse and you will have exactly what the scientific community has always declared how a vortex works. This relationship between the two accelerating velocities has another principle to it. This principle is the 100% gravitational force will accelerate faster than the velocity of the water moving to the pipe or sliding down the pipe in order for this to happen. The 100% gravitational force has to take a lesser degree of a angle as it runs into the wall that is presented by the water that is sliding down the pipe. The more it rotates the closer it gets to zero angle. This cannot actually get to zero angle as this would cause the vortex to stop working, but it can in theory approach zero angle or infinity. This is very important, if you decide to look into how a Black Hole actually works or function. I will discuss this a little further down..

This basic physics dictates how a self generating vortex must start rotating and in some cases will continue under this process or phase. This includes a vortex that is formed in a sink, tornadoes, hurricanes, how the planets, stars, solar system, galaxies were formed and how Black Holes actually work or function.

You can see that this little miss physics will have major importance, to the scientific world.

I am going to explain how I see the above self generating vortex actually began to rotate.

When a cold front moves South and pushes up large quantities of unstable warm air to the point where it becomes to rest on top of the eye wall of a super cell storm. This unstable air fines or creates a whole through the eye wall where it attempts to flow through the opening. This unstable air is held back by the volume of air that is above it until the point where it starts rotating. This is the same basic form a that is described above. A hurricane works on the same basics principle, but with a little different beginning. This process worked with gravity, but also works with anything that emulates the same process.( I believe this process or phase also applies to the Golden Phi Ratio.) The energy coming from the ocean is trying to rise up against the force of the dense air trying to go back to the water. It must start rotating in order for the energy to accelerate upward. This causes a low pressure to form with a center that wants the air above it to flow into it, but is held back by the air above it, so it continues to rotate. This is very basic, of how a hurricane starts his rotation.

The formation of the planets, stars, solar system and galaxies work under the same basic principle. A gas that keeps getting denser because of the gravitational force will eventually get to a point, a cascading point where the gravitational force requires a gas above it to accelerate faster than it is capable of doing this cascading event is what causes all of the planets and stars rotation in the Milky Way gallery to be traveling at the same velocity. Stars are formed under the same principles and once a gas cloud is large enough and dense enough, the collapsing gas cloud will start to rotate and form a star. The planets may form in the same process or as in around the base of a tornado, you can spot smaller vortices rotating around its base. You can also see how these smaller vortices would migrate into a gas cloud and start the formation of a planet. I think this will also explain how the water was created that is on earth. The frictional force that was created in the vortex that created Earth also oxidize the hydrogen and oxygen that was in the gas cloud that formed our solar system and planets

This is where he gets interesting for the ones that believe in Singularity, Dark Matter, Dark Energy, and all the other goblins that is created from Singularity.

When a star reaches a certain size that the distance between the outer layer of the star and the center is sufficient enough that when it collapses during a supernova. The following will happen. Gravitational force dictates there is only one option for it to take.

The principle that I described above that requires the rotating 100% energy force to take a lesser and lesser angle becomes very important this point. When you start dealing with distances that exists in a collapsing supernova the rotational aspects of this principle requires it to approach zero angle. As you approach zero angle. You also approach infinity in velocity. This infinity velocity is not the speed of light, but exceeds the speed of the Big Bang. There is another principle that I have not discussed involved in this process. This principle requires that the gravitational force is the beginning dominant force, but the centrifugal force at some point becomes the dominant force. Because of this principle, Einstein's theory on singularity cannot exist. This explains how a pulsar gets it's rotational velocity. A star that is just not big enough to become a black hole ends up being a pulsar.

Although I may have injected some hypothesizing into the above statement. It is based on the basic principles of physics. I think I will add another hypothesis to this. In order for the tornado vortex to operate it has to take in heavier denser air in and through the centrifugal force releases air that is less dense. The same process must be going on in the inner workings of the Black Hole. In the beginning when a black hole is forming. It must first stop the collapse of the star and through the centrifugal force rips apart all matter and converted into energy. All matter that falls into the black hole will also be destroyed in this manner, the physics that dictate the velocities must go to infinity indicate to me at some point it will actually start sucking space as we know it back into it. I theorize the universe will be sucked back into what ever the Big Bang came from. It is like putting the genie back in the bottle. Black Holes will eventually suck all or consume all of the universe, and when there is no more space to consume there will be a Big Bang to start it all over again. This principle that governs this is mentioned above, the vortex cannot be sustained under these principles when the basin become small relative to the vortex.

True science can stand on its own, anything else has to be supported by man's reasoning.
