# Solving the $\boldsymbol{n}_{\mathbf{1}} \times \boldsymbol{n}_{\mathbf{2}} \times \boldsymbol{n}_{\mathbf{3}}$ Points Problem for $\boldsymbol{n}_{\mathbf{3}}<6$ 

Marco Ripà<br>sPIqr Society, World Intelligence Network<br>Rome, Italy<br>e-mail: marcokrt1984@yahoo.it

#### Abstract

In this paper, we show enhanced upper bounds of the nontrivial $n \_1 \times n \_2 \times n \_3$ points problem for every $n_{-} 1 \leq n_{-} 2 \leq n_{-} 3<6$. We present new patterns that drastically improve the previously known algorithms for finding minimum-link covering paths, solving completely a few cases (e.g., n_1 = n_2 $=3$ and n_3=4).

Keywords: Graph theory, Topology, Three-dimensional, Creative thinking, Link, Connectivity, Outside the box, Upper bound, Point, Game.

2010 Mathematics Subject Classification: 91A43, 05C57.

## 1 Introduction

The $n_{1} \times n_{2} \times n_{3}$ points problem [12] is a three-dimensional extension of the classic nine dots problem appeared in Samuel Loyd's Cyclopedia of Puzzles [1-9], and it is related to the well known NP-hard traveling salesman problem, minimizing the number of turns in the tour instead of the total distance traveled [1-15].
Given $n_{1} \cdot n_{2} \cdot n_{3}$ points in $\mathbb{R}^{3}$, our goal is to visit all of them (at least once) with a polygonal path that has the minimum number of line segments connected at their end-points (links or generically lines), the so called Minimum-link Covering Path [3-4-5-8]. In particular, we are interested in the best solutions for the nontrivial $n_{1} \times n_{2} \times n_{3}$ dots problem, where (by definition) $1 \leq n_{1} \leq n_{2} \leq n_{3}$ and $n_{3}<6$.
Let $h_{l}\left(n_{1}, n_{2}, n_{3}\right) \leq h\left(n_{1}, n_{2}, n_{3}\right) \leq h_{u}\left(n_{1}, n_{2}, n_{3}\right)$ be the length of the covering path with the minimum number of links for the $n_{1} \times n_{2} \times n_{3}$ points problem, we define the best known upper bound as $h_{u}\left(n_{1}, n_{2}, n_{3}\right) \geq h\left(n_{1}, n_{2}, n_{3}\right)$ and we denote as $h_{l}\left(n_{1}, n_{2}, n_{3}\right) \leq h\left(n_{1}, n_{2}, n_{3}\right)$ the current proved lower bound [12].
For the simplest cases, the same problem has already been solved [3-12]. Let $n_{1}=1$ and $n_{2}<n_{3}$, we have that $h\left(n_{1}, n_{2}, n_{3}\right)=h\left(n_{2}\right)=2 \cdot n_{2}-1$, while $h\left(n_{1}=1, n_{2}=n_{3} \geq 3\right)=2 \cdot n_{2}-2$ [6]. Hence, for $n_{1}=2$, it can be easily proved that

$$
h\left(2, n_{2}, n_{3}\right)=2 \cdot h\left(1, n_{2}, n_{3}\right)+1=\left\{\begin{array}{lll}
4 \cdot n_{2}-1 & \text { iff } & n_{2}<n_{3}  \tag{1}\\
4 \cdot n_{2}-3 & \text { iff } & n_{2}=n_{3}
\end{array}\right.
$$

## 2X3X5 SOLUTION (trivial): <br> 11 lines

## NO INTERSECTION

Figure 1. A trivial pattern that completely solves the $2 \times 3 \times 5$ points puzzle.

## 2X5X5 SOLUTION (trivial):

17 lines
NO INTERSECTION

Figure 2. Another example of a trivial case: the $2 \times 5 \times 5$ points puzzle.

Therefore, the aim of the present paper is to solve the ten aforementioned nontrivial cases where the current upper bound does not match the proved lower bound.

## 2 Improving the solution of the $\boldsymbol{n}_{1} \times \boldsymbol{n}_{\mathbf{2}} \times \boldsymbol{n}_{\mathbf{3}}$ points problem for

 $n_{3}<6$In this complex brain challenge we need to stretch our pattern recognition [7-10] in order to find a plastic strategy that improves the known upper bounds [3-13] for the most interesting cases (such as the nontrivial $n_{1} \times n_{2} \times n_{2}$ points problem and the $n_{1} \times n_{1} \times\left(n_{1}+1\right)$ set of puzzles), avoiding those standardized methods which are based on fixed patterns that lead to suboptimal covering paths, as the approaches presented in [2-8-11].

Let $3 \leq n_{1} \leq n_{2} \leq n_{3} \leq 5$, a lower bound of the $n_{1} \times n_{2} \times n_{3}$ problem is given by [12]

$$
\begin{equation*}
h_{l}\left(n_{1}, n_{2}, n_{3}\right)=\left\lceil\frac{n_{1} \cdot\left(2 \cdot n_{2} \cdot\left(n_{3}+1\right)-n_{1}-1\right)-2}{n_{3}+n_{2}-2}\right\rceil-1 \tag{2}
\end{equation*}
$$

The current best results are listed in Table 1, and a direct proof follows for each nontrivial upper bound shown below.

Table 1: Current solutions for the $n_{1} \times n_{2} \times n_{3}$ points problem, where $n_{1} \leq n_{2} \leq n_{3} \leq 5$.

Figures 3 to 12 show the patterns used to solve the $n_{1} \times n_{2} \times n_{3}$ puzzle (case by case). In particular, by combining the (2) with the original result shown in figure 4 , we obtain a formal proof for the $3 \times 3 \times 4$ points problem.

## 3X3X3 SOLUTION CONSIDERING TWO DIFFERENT PATHS:

Figure 3. $h_{u}(3,3,3)=h_{l}(3,3,3)=14$. This solution has been proved to be optimal [12-13].

Figure 4. The $3 \times 3 \times 4$ puzzle has finally been solved. $h_{u}=h_{l}=15$ and no crossing lines.

Figure 5. Best known upper bound of the $3 \times 4 \times 4$ puzzle. $19=h_{u}=h_{l}+2$.

## $4 \times 4 \times 4$ best upper bound:

## 23 lines

Figure 6. An original pattern for the $4 \times 4 \times 4$ puzzle. $23=h_{u}=h_{l}+1$ [13].

3X3X5 best upper bound:

Figure 7. Best known upper bound of the $3 \times 3 \times 5$ puzzle. $16=h_{u}=h_{l}+1$.
$3 \times 4 \times 5$ best upper bound:
20 lines

Figure 8 . Best known upper bound of the $3 \times 4 \times 5$ puzzle. $20=h_{u}=h_{l}+2$.

## $3 \times 5 \times 5$ best upper bound:

24 lines

Figure 9 . Best known upper bound of the $3 \times 5 \times 5$ puzzle. $24=h_{u}=h_{l}+4$.
$4 \times 4 \times 5$ best upper bound: 26 lines

5
Figure 10. Best known upper bound of the $4 \times 4 \times 5$ puzzle. $26=h_{u}=h_{l}+2$.
$4 \times 5 \times 5$ best upper bound:
31 lines

Figure 11. Best known upper bound of the $4 \times 5 \times 5$ puzzle. $31=h_{u}=h_{l}+4$.

## $5 \times 5 \times 5$ best upper bound:

36 lines

Figure 12. Best known upper bound of the $5 \times 5 \times 5$ puzzle. $37=h_{u}=h_{l}+4$ [13].
Finally, it is interesting to note that the improved $h_{u}\left(n_{1}, n_{2}, n_{3}\right)$ can lower down the upper bound of the generalized $k$-dimensional puzzle too. As an example, we can apply the aforementioned 3D patterns to the generalized $n_{1} \times n_{2} \times \ldots \times n_{k}$ points problem using the simple method described in [12].
Let $k \geq 4$, given $n_{k} \leq n_{k-1} \leq \cdots \leq n_{4} \leq n_{1} \leq n_{2} \leq n_{3}$, we can conclude that

$$
\begin{equation*}
h_{u}\left(n_{1}, n_{2}, n_{3}, \ldots, n_{k}\right)=\left(h_{u}\left(n_{1}, n_{2}, n_{3}\right)+1\right) \cdot \prod_{j=4}^{k} n_{j}-1 \tag{3}
\end{equation*}
$$

## 3 Conclusion

In the present paper we have drastically reduced the gap $h_{u}\left(n_{1}, n_{2}, n_{3}\right)-h_{l}\left(n_{1}, n_{2}, n_{3}\right)$ for every previously unsolved puzzle such that $n_{3}<6$. Moreover, we can easily disprove Bencini's claim that $h_{u}(3,3,4)=17=h_{l}(3,3,4)$ (see [2], page 7, lines 2-3), since $h_{u}(3,3,4)=15=h_{l}(3,3,4)$, as shown by combining (2) with the upper bound from figure 4. We do not know if any of the patterns shown in figures 5 to 12 represent optimal solutions, since (by definition) $h_{l}\left(n_{1}, n_{2}, n_{3}\right) \leq h\left(n_{1}, n_{2}, n_{3}\right)$. Therefore, some open questions about the $n_{1} \times n_{2} \times n_{3}$ points problem remain to be answered, and the research in order to cancel the gap $h_{u}\left(n_{1}, n_{2}, n_{3}\right)-h_{l}\left(n_{1}, n_{2}, n_{3}\right)$, at least for every $n_{3} \leq 5$, is not over yet.
